Introduction

About Analytica

This introduction explains:

• How to use this manual
• How to install Analytica
• The online help system
• How to access Analytica example models
• What’s new in Analytica release 4.0.
• Typographic conventions used in this guide
Welcome!

This User Guide describes how to use Analytica 4.0. If you are new to Analytica, we invite you to start with the Analytica Tutorial to learn the essentials. Most people find they can work through the Tutorial quite rapidly. You may then want to read a few sections of the User Guide listed in the next section to learn more key concepts. You may consult the rest of this guide as a reference when you need more depth. For still more, visit Anawiki (the Analytica Wiki online at http://www.lumina.com/wiki), including Tips, Libraries, and Reference.

If you can’t find what you want, or have comments on our documents or software, please email us at Lumina at support@lumina.com. We are always glad to hear from Analytica users.

If you don’t read manuals

Experienced modelers find most Analytica features intuitive. But, it’s helpful to get a good grasp of some key concepts so you can get up to speed rapidly. Here are a few chapters that you may find especially helpful to review:

**Chapter 5: Building effective models** offers guidelines for creating effective models, distilled from the experience of master modelers. It offers a practical guide for building effective models that are clear, reliable, and focus on what really matters — the decisions, objectives, and key uncertainties. These tips are not specific to Analytica, but we designed Analytica to make them especially easy to follow.

**Chapter 6: Creating lucid diagrams** gives tips on how to create influence diagrams that are truly lucid and elegant — and how to avoid incomprehensible spaghetti.

**Chapter 11: Arrays and Indexes** explains Analytica’s Intelligent Arrays™. After you grasp the essentials, they let you build complex multidimensional models with surprising ease. But, you may find they take a little getting used to, particularly if you have spent a lot of time with spreadsheets or programming with arrays. We recommend that even — perhaps especially — experienced modelers review this chapter.

**Chapter 13: Expressing uncertainty** discusses how to select appropriate probability distributions to express uncertainties. It also provides an overview of how Analytica computes probability distributions using Monte Carlo and other random sampling methods, and your options for controlling and displaying probabilistic values.

**Chapter 20: Procedural programming** With Analytica, you can create large and sophisticated models without procedural programming. But, if you really want to write complex procedural functions, read this chapter to understand Analytica as a programming language.

Hardware and software requirements

To use Analytica, you need the following quite modest minimum configuration:
Introduction

About Analytica

Installation and license codes

- 486-66 MHz (Pentium 500 MHz+ recommended)
- 20 MB disk space
- 256 MB RAM (2 GB recommended for large models)
- 8-bit color display
- Windows 98, 2000, NT 4, ME, XP, or Vista

It helps to have a faster CPU, and, especially, more RAM for large models. Analytica will benefit from up to 3 GB RAM if you have it. It is also handy to have a large screen, or even multiple screens, when working with a large model.

Installation and license codes

After downloading the Analytica 4.0 installer from www.lumina.com, or inserting the Analytica CD-ROM into your CD or DVD drive, just double-click the installer to start installation. It will install onto your hard drive the executable software, all documentation as Adobe PDF files, plus a range of Analytica libraries and example models. If you have installed an earlier release of Analytica, such as 2.0 or 3.1, the installer will leave it there, so you can run either version.

The setup program will ask you to confirm the directory name in which to install Analytica, by default, C:\Program Files\Analytica 4.0. Most users can accept the defaults.

License codes

You need a license code to activate the software. Lumina will email you a license code when you download a Player or Trial edition, or when you purchase a copy. If someone else purchased Analytica for you, you may need to ask that person to forward you the email with your license code.

During installation, Analytica will prompt you for a license code. You can copy and paste the code from the email into the field, or just retype it. The license code activates the specified edition of Analytica, e.g., Player, Trial, Professional, Enterprise, or Optimizer.

Stale license codes

Each license code goes stale a few days after it is generated. If yours is stale — perhaps, because you didn’t install Analytica right away, or, later, if you want to move Analytica onto another computer — fear not! Click the URL on the registration screen, or go to http://www.lumina.com/ana/stale. Provide the requested information, and it will immediately email you a fresh license code. This mechanism is designed to prevent unauthorized use of old license codes. Authorized users can always get a fresh license code.

Expiration dates

Some license codes — notably, for a Trial or an edition licensed per year — have a limited life, after which they expire. After expiration, Analytica reverts to the Player edition, so you will still be able to open, view, and evaluate your models. You just won’t be able to make or save changes. Expiration is not the same as going stale. To reactivate Analytica after expiration, you may need to purchase a copy.

When you purchase a license or upgrade to another edition

You don’t need to download and reinstall Analytica again when you purchase a license after testing the free trial, or if you want to upgrade from, say, the Professional to Enterprise edition. Just select Update License from the Help menu in Analytica and enter your new license code into the Licensing Information dialog.
Analytica Decision Engine (ADE) is a different application from Analytica, and requires a new installation, even if you already have another edition of Analytica installed.

To upgrade to a minor or patch release
When you upgrade a licensed copy with a patch or minor release (e.g., 4.0 to 4.0.1), simply run the installer. It will replace the older release and reuse your existing license code.

To upgrade to a major release
You can install Analytica 4.0 and retain an earlier major release, such as Analytica 3.1, on your computer. You will need a new license code for the new release.

To uninstall Analytica
After confirming that Analytica 4.0 is working, you will usually want to uninstall the earlier release. To uninstall Analytica 3.1 — or any release:

1. From the Windows Start menu, open the Control Panel.
2. Click Add or remove programs.
3. Find Analytica 3.1 (or whichever release you want to remove) and click Change/Remove button to start the Wizard.
4. In the InstallShield Wizard dialog, select the Remove radio button, and click Next.
Editions of Analytica

Analytica is available in these editions. See the next page for a list of key features by edition:

**Player**
Lets you review and run Analytica models without having to purchase a license. With the Player edition, you can change designated inputs, run the model, view results, and examine selected model diagrams and variables. It does not let you create new models, make changes other than to selected inputs, or save models.

**Professional**
Provides most features, including the ability to create, edit, and save models.

**Trial**
A free edition of Analytica that provides the full functionality of Analytica Professional for a limited time, usually 15 days. After that, it reverts to the functionality of Analytica Player, so you can still view and run any models you have created, but not save changes.

**Power Player**
Like the Player, it lets you review models, change inputs, and view results, and does not let you create or edit models. Unlike the Player, it does let you save models with changed inputs. It also supports models that use Enterprise features, including database access, Huge Arrays, and the Profiler. See Chapter 22, “Analytica Enterprise” for details.

**Lite**
Available to qualified educational users only for teaching and research. It has the features of the Professional edition, except: No OLE linking, Outline Window, Advanced function libraries, nor ability to create input and output nodes and forms.

**Enterprise**
Offers all the features of Analytica Professional, plus Huge Arrays, reading and writing databases, profiling for analysis of computational effort by variable, and obfuscation (encryption) of sensitive model elements. See Chapter 22, “Analytica Enterprise” for details.

**Optimizer**
Offers all the features of Analytica Enterprise, plus the Optimizer Library that provides powerful solver and optimization methods, including linear programming (LP), quadratic programming, and nonlinear programming (NLP). Optimizer is available as an extension to Analytica Enterprise, Power Player, and ADE. See the *Analytica Optimizer Guide* for details.

**The Analytica Decision Engine (ADE)**
ADE runs Analytica models on a server computer. It provides an Application Programming Interface (API) to provide access to view, edit, and run models from another application, including a web server. You can create a user interface to models via a web browser, so that many end users may view and run a model via the Internet. You will need Analytica Enterprise as the development tool to create models to run with ADE. The ADE Kit includes a license for Analytica Enterprise in addition to ADE.

Help menu and electronic documentation

Select the Help menu from the menu bar:

<table>
<thead>
<tr>
<th>Help</th>
<th>Options</th>
</tr>
</thead>
<tbody>
<tr>
<td>User Guide F1</td>
<td>Opens the User Guide showing chapters, sections, and subsections as an expandable outline, using bookmarks. Press the function key F1 as a shortcut.</td>
</tr>
<tr>
<td>Optimizer</td>
<td>Opens the Optimizer Guide (if you have Analytica Optimizer).</td>
</tr>
<tr>
<td>Tutorial</td>
<td>Opens the Analytica Tutorial as a PDF document in Adobe Reader.</td>
</tr>
<tr>
<td>Web tech support</td>
<td>Opens Lumina’s Analytica tech support web page in your default Web browser, with support information and links to frequently asked questions.</td>
</tr>
<tr>
<td>Email tech support</td>
<td>Starts an email message to send to Lumina tech support using your default email application.</td>
</tr>
<tr>
<td>Register</td>
<td>Opens a web page where you can register your copy of Analytica, and copies your license code into the required field.</td>
</tr>
</tbody>
</table>

**Tip**
Most users see the left-hand version of the menu starting with User Guide. The right-hand version appears if you have Adobe Acrobat Standard or Professional installed, which enable direct links into sections of a PDF document.

**Content outline F1**
Opens the User Guide showing chapters, sections, and subsections as an expandable outline, using bookmarks. Press the function key F1 as a shortcut.

**Function list**
Opens a page listing all functions, operators, and other constructs, classified by type. Click a name to jump to an explanation of how to use it. This is a fast way to find a function if you don’t know its name.

**Index**
Opens the User Guide to its alphabetized index. Select the first letter of the term from the bookmark outline, and click an entry to jump to its explanation.

**Find**
Opens the Find dialog box in Adobe Acrobat so you can search for a term.

**What’s new in 4.0?**
Opens “What’s new in Analytica 4.0?” in the User Guide.
Contact Lumina  Opens a dialog box with Lumina contact information: web links, phone numbers, email, and physical mailing address.

Update license  Opens the Licensing Information dialog box so you can review your or enter a new License Code or enter a new code to upgrade your copy of Analytica.

About Analytica  Opens the startup splash screen, mentioning the Analytica Edition, release number, and the name of the person to whom it is licensed.

Online help and electronic documentation

You can open the Tutorial, User Guide and Optimizer Guide (when available) from the Help menu, or press the F1 key to open the User Guide.

You can read and search these PDF documents using the Adobe® Reader available free from http://www.adobe.com. Some additional features are available if you purchase Adobe Acrobat Standard or Professional.

The expandable outline

Click a section title to view that section. Click or icons to expand and contract chapters and sections of the outline.

Appendix H: Function list

If you can’t remember the name of a function, go to this page. It lists functions and system variables by functional groups. From here, click a function name to jump to its full description.
Introduction

About Analytica

Alphabetical index

If the search box finds too many occurrences of a term, try the Alphabetical Index in the bookmarks: It usually links to the best explanation for each term.

Normally, usually, and defaults

Sometimes this guide says “normally it does this” or “usually it does that.” This isn’t because Analytica is unpredictable, or because we’re just addicted to uncertainty. It’s because Analytica has a lot of preference and style options, and it’s often simpler to say “normally” or “usually” when we mean “with the standard defaults.”

Typographic conventions in this guide

<table>
<thead>
<tr>
<th>Example</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>behavior analysis</td>
<td>Key terms when introduced. Most of these terms are included in the Glossary</td>
</tr>
<tr>
<td>Diagram</td>

</tr>
<tr>
<td>Sequence()</td>
<td>Name of a variable or function in Analytica</td>
</tr>
<tr>
<td>Price - DownPmt</td>
<td>Expressions, definitions, example code</td>
</tr>
<tr>
<td>10^7 → 10M</td>
<td>In example code, this means that the variable or expression before the “→” generates the result after it</td>
</tr>
<tr>
<td>Enter, Control+a</td>
<td>A key or key-combination on the keyboard. A letter, such as “a”, may be lower- or uppercase</td>
</tr>
</tbody>
</table>

Code examples

This guide includes snippets of code to illustrate features, for example:

Index N := [1, 2, 3, 4, 5]
Variable Squares := N^2
Sum(Squares, N) → 55

This code says that there are two objects, an Index I and a variable Squares. You would create these objects in a Diagram window by dragging from the node toolbar into the diagram (see “Creating and editing nodes”). You would enter the expressions, [1, 2, 3, 4, 5] and N^2 into their definitions (see “Creating or editing a definition”). You would not enter the assignment “:=”. The last line says that the expression Sum(Squares, I) evaluates to the result 55 after the “→”. You might include that expression in the definition of third variable.

Array examples

We use these typographic conventions to show Analytica arrays:

- An index or list and its values
  
  N:

  1 2 3 4 5

- A one-dimensional array, Squares:
Introduction

About Analytica

User guide examples folder

The Examples folder distributed with Analytica includes User Guide Examples as a subfolder. It contains Analytica models used in Chapters 9, 10, 11, 12, 14, 15, 16, and 17. Open these models to see the examples in more detail.

See Chapter 8 of the Tutorial for a summary of the models in the Examples folder.

What’s new in Analytica 4.0?

These are highlights of new and improved features in release 4.0.

User interface

Graphs and charts

We completely rewrote the graphing and charting engine, adding a wide range of new styles and options. The Graph Setup dialog now has six tabs:

- Chart type tab includes stacked bars, filled areas with transparency, using symbol shape and size to indicate extra dimensions, 3D effects on bar charts, cylinders or boxes, and changing line width. It lets you swap horizontal (X) and vertical (Y) axes, e.g., to create horizontal bars for tornado diagrams.

- Axis tab offers log scales, reversed scales, and categorical scale. You can save axis settings as defaults associated with corresponding index variables. Graphing is much smarter in choosing which dates to display along an axis — by week, month, quarter, or year.

- Style tab lets you change colors of grid and frame — in addition to style of the grid, frame, tick marks, and key.
• **Text** tab lets you change the font type, size, style, and color for titles and labels. You can also rotate labels for axis tick marks to prevent overlaps, say for long text values.

• **Background** tab now lets you set a color or color gradient for the background of the entire chart, plot area, or key.

• **Preview** tab lets you look at the effects of the options you have selected before you decide to accept them. You can apply new graph settings to the current graph, or as defaults for all graphs.

See “Graph setup dialog box” for more information.

**Graph style templates** let you apply and reuse a collection of graph settings, for a consistent style for a model or your entire organization. See “Graph templates”

Graphing associates settings with the view so that it changes appropriately when you pivot or change the uncertainty view.

**XY comparison** now lets you plot one slice against another slice of an array variable over the Comparison index, as well as one variable against another. See “XY comparison”

### Tables

In graphs or tables, you can **reorder slicer** indexes (any graph indexes not shown on horizontal axis or key) simply by dragging them.

You can create smarter end-user interfaces by putting **dropdown** menus in cells of an edit table, using **Choice()** to let end users select from a list of options. See “Choice menus in an edit table”. When viewing a table, using **Find** from the **Object** menu (**Control+F**) lets you search for selected text.

The new **SubTable** function lets you define a variable as a subset of another edit table — any edit to a subtable makes the same change to its parent table, and vice versa. See “SubTable”

**Smart table splicing** controls how an edit table changes if its indexes change, e.g., editing a label or adding an item or index. You can specify default values for new cells created by expanding and index.

### Number, currency, dates, and languages

Analytica is less US-centric: Number formats offer multiple currency symbols and flexible date formats, with format and language of days and months depending on Windows regional settings. You can paste text containing accents and non-English characters (Ascii>127) into **object** attributes and diagram nodes. The date functions **DateAdd**, **DatePart**, and **Today** add flexibility for computing dates. See “Number formats”

### Scroll wheel and keyboard shortcuts

The **scroll wheel** on your mouse scrolls windows (diagrams, tables, and objects), vertically, or horizontally when you press **Control**. Dozens of **new keyboard shortcuts** let you navigate and select cells and regions from tables (like Microsoft Excel). When editing a diagram, shortcuts **Control+1**, **Control+2**, etc., add a new decision node, variable node, etc. **Control+e** now opens the script of a button, just like it opens the definition for a variable or function.

### Influence diagrams

To make diagrams neater, use the new **Align**, **Make same size**, and **Space evenly** options from the **Diagram** menu (see “Arranging nodes to make clear diagrams”). You can now add web links to a diagram as URLs in a text node. An optional red flag in node shows which objects have descriptions (see “Preferences dialog”).

Here’s an alternative to drawing arrows: When you’re editing a definition in the **Attribute** panel below a **Diagram** window, **Alt-click** another node in the diagram to insert its identifier into the definition.
The Application

Auto save Analytica writes each change to an auto save file, so you won’t lose any work after a software or hardware crash. Next time you start the model, it asks if you want to use the backup or revert to the previously saved version.

CPU sharing It shares CPU nicely with other applications, and doesn’t hog the CPU when it is active.

Multiple screens Analytica now supports editing diagrams across multiple screens for a larger desktop.

Probability distributions and statistical functions

Discrete or continuous When graphing a probability distribution, it is smarter about displaying a probability mass function for a discrete variable or density function for a continuous variable. If needed, you can override this, by specifying Continuous or Discrete in the Domain attribute, or checking Categorical in the Axis scale tab in Graph set up. See “The domain attribute and discrete variables”.

New functions Random( ) generates single random sample from any distribution. Shuffle(x, i) randomly shuffles an array. Pdf(x) and Cdf(x) return the estimated probability density or cumulative probability functions as arrays. The system variable IsSampleMode returns true in prob mode, false in mid mode, so you can tell the evaluation mode within a function. See “Random(expr)”, “Shuffle(a , i)”, and “PDF(X) and CDF(X)”. 

Over parameter You can create an array of independent probability distributions over one or more indexes by adding optional Over parameter to a univariate probability distribution, e.g., Normal(0, 1, Over: I, J). See “Over indexes as parameters to probability distributions”.

Extended functions Lognormal uses mean and stddev (standard deviation) as an alternative to median and gsd (geometric standard deviation). Truncate(x, min, max) accepts min and/or max threshold parameters and preserves sample ordering, and hence rank correlations. Uniform(min, max, integer) adds the optional parameter integer to specify that values be integers in the range. CumDist(p, r, i, smooth) adds an optional Smooth parameter to control interpolation. See “Parametric continuous distributions” and “Truncate(u, min, max)”. 

Uncertain parameters Many distribution functions are much faster, especially when their parameters are uncertain (hierarchical distributions). Gamma, Binomial, Gammaln are more accurate for extremely large or small parameter values. See “Gammaln(x, a, b)”, “Binomial(n, p)”, and “Gammaln(y, a, b)”. 

Multivariate Distributions library New distributions include MultiUniform and UniformSpherical, generalized Dist reshape, functions for creating time series with serial correlations, and uncertainty about regression coefficients. See “MultiUniform(cm, i, j, lb, ub)”, ”Dist reshape(x, newdist)”, and ”UniformSpherical(i, r)”. 

Distribution Variations library New distributions include Smooth_fractile, Warp_dist, Erlang, Pareto, Rayleigh, Lorenzian, NegBinomial, InverseGaussian, Wald. 

Running index for statistics By default, the running index defining which dimension statistical functions operate over is Run, the index over random samples. You may specify a different running index as the last parameter to any statistical function if you want something other than Run, e.g., Variance(X, I) computes the variance over index I, even if X is not uncertain. This renders obsolete the Data Statistics Library.ana, previously included with Analytica.

Importance weighting Importance weighting is a powerful enhancement to Monte Carlo simulation that lets you get more information from fewer samples; it is especially valuable for risky situations with a small probability of an extremely good or bad outcome. Instead of treating
all samples as equally likely, you can set **SampleWeighting** to generate more samples in the most important areas. Graphs of probability distributions and statistical functions downweight sample values with **SampleWeighting** so that their results are unbiased. You can modify **SampleWeighting** interactively to reflect different input distributions and so rapidly see the effects on results without having to rerun the simulation. In the default mode, it uses equal weights, as before, so you don’t have to worry about importance sampling unless you want to use it. See “Importance weighting”.

**Weights for statistics** By default, statistics functions use **SampleWeighting** when you are using importance sampling. You may also provide an optional parameter **W** to a statistical function to specify a nondefault set of weights. For example, **Mean(X, W: X > 0)** gives the mean of **X** conditional on **X** being positive.

**New functions and language extensions**

**List of variables** If you define a variable as a list of variables, e.g., \( X := \{A, B\} \), it creates the list variables as the index value of **X**. This is very convenient for comparing several variables. In a table view, it usually shows the title of each variable in the index. If you double-click a variable title, it opens its Object window. You can add another variable **C** to the list simply by drawing an arrow from **C** to **X**, or remove it by redrawing the arrow.

**IndexVals** If you define **x** as a list of variables, as above, it saves the list of variables as its index in its **IndexVals** attribute. You can get these with the **IndexVals(X)** function. If you pass **X** to a function as an **Index** parameter, it uses **IndexVals**.

**FOR iteration index** In **FOR j := x DO e**, **x** can now be any expression that evaluates to an array. It evaluates **e** with **j** set successively to each cell (atom) of **x**. The value of the FOR expression is an array with the same index(es) as **x**.

You can now subscript an expression, as in \((A+B)[I=x]\).

**Position operator @** \(@J\) returns the position (an integer from 1 to n) of each element of index **J**. \(X[@J = 2]\) is equivalent to **Slice(A, J, 2)**. **PositionInIndex(a, u, i)** gives the position **n** in index **i** for which **a[n] = u**. See “@: Index Position Operator”.

**Slice assignment** \(x[I=y] := b\), now lets you assign to a cell or slice of a local variable **x**, allowing you to write some algorithms much more efficiently. See “Assigning to a slice of a local variable”.

**Argmin and Argmax** The new **Argmin(x, i)** and existing **ArgMax(x, i)** can both now work over multiple indexes, and return the value or position of the indexes containing the minimum or maximum value. See “Argmin(a, i)” and “Argmax(a, i)”.

**Trig functions** We have added the inverse trigonometric functions **ArcCos**, **ArcSin**, **ArcTan**, and hyperbolic functions **CosH**, **SinH**, and **TanH**. They use or return degrees, not radians. See “Math functions” and “Advanced math functions”.

**Rank** Lets you specify mid, lower, or upper rank in the event of a tie.

**RunConsoleProcess** Lets you run another application from Analytica. It can pass data as function parameters or via data files. It can run a process concurrently with Analytica or wait for its result to be computed. See “RunConsoleProcess(program, cmdline, stdIn, block)”.

**System functions** **GetRegistryValue()** returns selected values from the computer registry, such as the default directory for model or data files. **ShowPdfFile()** shows an Adobe PDF file, for example, to open PDF documentation for a model. **AnalyticaLicenseInfo** returns information about the license, such as its edition, beta status, expiration date, or user ID.
**TypeOf(X)**

Returns the type of each atom in X as a text value, including “Number”, “Text”, “Reference”, or “Null”. If X is a handle, it returns the class of the object pointed to by X.

**Handles**

A pointer to an object, such as a variable or module. The Inputs, Outputs, or Contains attributes create a list of handles to objects. With handles, you can write functions that navigate around a model, e.g., to get a list of the inputs or all ancestors of a variable. The new function Handle(X) gives a handle to X instead of its value. HandleIdentifier(T), as you might expect, gives a handle if T is the text identifier of an object. IndexesOf(A) returns a list of handles of the indexes of array A.

**Optional and repeated parameters**

The qualifier Optional in the parameters of a function specifies that the parameter is optional. You can also supply a default for when the parameter is omitted. The repeat qualifier “...” lets you define a function that takes one or more parameters of the given type.

**Multiply by zero**

0*NaN and 0*INF now give a warning and return NaN, consistent with the IEEE 754 and SANE arithmetic standards. Earlier releases simply returned 0.

---

**Analytica Enterprise Edition**

These features are available in the Enterprise edition, and may be used from the Power Player edition:

**Database functions**

You can now assign result of DbQuery to a local index variable, letting you create a single variable or function to return a relational table, without having to create auxiliary global indexes for rows and columns.

**MDX hypercube access**

The new MDXQuery function supports the standard MDX language for querying and writing to multidimensional OLAP hypercube databases, such as offered by Microsoft SQL Server Analysis Services. It greatly expands ways to integrate Analytica with business intelligence and related applications.

**MDTable**

Now lets you specify the first N columns of X as coordinates and the rest as measures, as used in a fact table, the format used to specify OLAP hypercubes. It also lets you pass it a conglomeration function. See “MDTable(t, rows, cols, vars, conglomFn, missingVal)”.

**Performance Profiler library**

This library now shows a sorted table with memory and time used by each variable and function. Double-click any object title to open its Object window.

---

**Analytica Optimizer**

The Analytica Optimizer uses the new 7.0 release of the Premium Solver from Frontline Systems. New features include: Grouped Integer variable type, where a solution must assign a different integer from 1 to n to each variable in the group. The quadratic programming solver, QpDefine, now supports quadratic constraints in additional to linear constraints. SolverInfo function returns information about the current solver. The solvers offer a more flexible option for passing all parameters as a single array of parameters, labeled by parameter name in the index. You can add yet more powerful solvers, including OptQuest, Knitro NLP, Mosek SOCP and NLP, and Xpress LP, QP and MIP (priced separately). See the Optimizer Guide or What’s New in Optimizer 4.0 for more.

**Generalized Regression library**

Offers Logistic_Regression and Probit_Regression, using the Optimizer. See “Logistic_Regression(Y, B, I, K)” and “Probit_regression(Y, B, I, K)”.
This chapter introduces the basics of how to open and view an Analytica model, generate results, and print them, including:

- Start up a model
- Explore its Diagram window
- Explore its Object window
- Explore its Result window
- Print the contents of windows
To open or exit a model

Models  An Analytica model is a collection of variables, modules, and other objects intended to represent some real-world system you want to understand. Between sessions, a model is stored in an Analytica document file with the file type ".ana".

To open a model  The simplest way to open an existing model is just to double click the icon for the model file in the Windows directory.

Another way to open a model is to:

1. Start up Analytica — by double-clicking the icon of the Analytica application, or selecting Analytica from the Windows Start menu. Analytica will open a new, untitled model.

2. In the top left of the Analytica application window, press on the File pull-down menu, and select Open Model. A directory browser dialog will appear to let you to find the model file you want.

Whichever way you start a model, Analytica will show this progress bar as it reads in the model file:

![Reading from File](image)

Tip  Click the Stop button if you change your mind and decide not to open the model. It will stop reading, resulting in a partially loaded model.

Next, it shows a progress bar as it checks the definitions of variables and functions in the model:

![Checking Definitions](image)

Tip  If you click the Stop button, it will stop checking. Diagrams may have missing arrows and cross-hatched nodes indicating unchecked definitions. If you later ask to show the result of a variable, it will check any variables needed. Thus, clicking stop here simply defers some checking, and causes no problems with the model.

If the model contains any variables whose definitions are missing or invalid, it will let you know by listing them in the Invalid Variables window (see “Invalid variables”). You can still compute results for variables with valid definitions, as long as they don’t depend on variables whose definition is invalid.

To close a model  To close a model, select Close Model from the File menu. If you have made any changes to the model, a dialog box asks you whether you want to save the changes.
before closing — except if you are using the Player Edition, which doesn’t let you save a changed model.

**To open another model**
Analytica can open only one model at a time. To switch to another model, first close the model, by selecting Close Model from the File menu. Then select Open Model from the File menu. A dialog box prompts you to locate and open another model.

**To exit Analytica**
To exit (or quit) Analytica, select Exit from the File menu. If you have made any changes to the model, it will prompt you to save your model first (if you are not using the Player Edition).

## Diagram window

When you open a model it shows a Diagram window. This window usually shows an influence diagram, like this:

![Influence Diagram Example](image)

Each node depicts a variable (thin outline) or module (thick outline). The node shape and color tells you its class — decision, chance, objective, module, and so on. The arrows in a Diagram window depict the influences between variables. An influence arrow from variable A to variable B, means that the value of A influences B, because A is in the definition of B. So, when the value of A changes, it may change the value (or probability distribution) for B.

In the diagram above, the arrow from Buying price to Cost to buy means that the price of the house affects the overall cost of purchasing it. The influence diagram shows the essential qualitative structure of the model, unobscured by details of the numbers or mathematical formulas that may underlie that structure. For more on using influence diagrams to build clear models, see Chapter 6, “Creating Lucid Influence Diagrams”.

### To view results
To view the value of a variable, first click its node to select it. Then click this Result button in the navigation toolbar to open a Result window showing its value as a table or graph. Chapter 2, “Result Tables and Graphs,” tells you more.
Chapter 1 Examining a Model

Classes of variables and other objects

The shape of a node indicates the class of the variable or other object:

A rectangle depicts a **decision variable** — a quantity that the decision maker can control directly. For example, whether or not you take an umbrella to work is your decision. If you are bidding on a contract, it is your decision how much to bid.

An oval depicts a **chance variable** — that is an uncertain quantity whose definition contains a probability distribution. For example, whether or not it will rain tomorrow is a chance variable (unless you are a rain god). And whether or not your bid is the winning bid is a chance variable in your model, although it is a decision variable for the person or organization requesting the bid.
A hexagon depicts an **objective variable** — a quantity that evaluates the relative value, desirability, or utility of possible outcomes. In a decision model, you are trying to find the decision(s) that maximize (or minimize) the value of this node. Usually, a model contains only one objective.

A rounded shape (with thin outline) depicts a **general variable** — a quantity that is not one of the above classes. It may be uncertain because it depends on one or more chance variables. Use this class initially if you're not sure what kind of variable you want. You can change the class later when it becomes clearer.

A rounded node (with thick outline) depicts a **module** — that is, a collection of nodes organized as a diagram. Modules can themselves contain modules, creating a nested hierarchy.

A parallelogram depicts an **index variable**. An index is used to define a dimension of an array. For example, **Year** is an index for an array containing the U.S. GNP for the past 20 years. Or **Nation name** is an index for an array of GNPs for a collection of nations (see "Introduction to arrays"). Indexes identify the row and column headers of a table, and the axes and key of a graph.

A trapezoid depicts a **constant** — that is, a variable whose value is fixed. A constant is not dependent on other variables, so it has no inputs. Examples of numerical constants are the atomic weight of oxygen (16) or the number of feet in a kilometer. It is clearer to define a constant for each such value you need in a model, so you can refer to them by name in each definition that uses it, rather than retyping the number each time.

A shape like an arrow tail depicts a **function**. You can use existing functions from libraries, and define new functions to augment the functions provided in Analytica. See Chapter 20, "Building Functions and Libraries."

This node is a **button** — when you click a button (in browse mode), it executes its script to perform some useful action. You can use buttons with any edition of Analytica, but you need Analytica Enterprise or Optimizer to create a new button. See “Creating buttons and scripts” on page 387.

### Selecting nodes

To view or change details of a variable or other object in a diagram, you must first select a node (or a set of nodes). You do this in much the same way as you select files or folders in the Windows File Browser, and most other applications:

- **To select a node**
  Simply click a node once to select it. Selected node(s) are highlighted with reverse color in browse mode, or with handles (little corner squares) in edit mode.

  You can also press the Tab key to select a node. Each time you press Tab, it selects the next node in the diagram, in the order the nodes were created. Control+Tab cycles through the nodes in the reverse sequence.

- **To select multiple nodes**
  Click a node while pressing the Shift key to add it to the set of selected nodes. You can remove a node from the selection by clicking it again while pressing Shift.

  In edit mode, you can also select a group of nodes by dragging the selection rectangle to enclose them. Press the mouse button in a corner of the diagram — say top left — and drag the cursor to the opposite corner — say bottom right. This will show the selection rectangle and select all nodes within the rectangle.
To deselect all nodes  Just click the background of the diagram outside any node.

The toolbar

The toolbar appears across the top of the Analytica application window. It contains buttons to open various views of the model, and to change between browse and edit modes.

Navigation toolbar

The first five buttons on the toolbar each open a window relating to the variable or the object selected in the active (frontmost) window:

- **Parent Diagram button:** Click to open the Diagram window for the module or model containing the object in the current active Diagram, Object, or Result window. It highlights the object you were viewing in the parent diagram. If you are viewing the top-level model, which has no parent, this button is grayed out. The keyboard shortcut is F2.
- **Outline button:** Click to open the Outline window. The outline highlights the object you were previously looking at. See “The Outline window”. The keyboard shortcut is F3.
- **Object button:** Click to open the Object window for the selected node in a diagram or the active module. See “The Object window”. The keyboard shortcut is F4.
- **Result button:** Click to open a Result window (table or graph) for the selected variable (see “The result window”). This button is grayed out if no variable is selected. If you have selected more than one variable, it will offer to create a compare variable that shows a result combining the values of all the variables. The keyboard shortcut is Control+r or F5.
- **Definition button:** Click to view the definition of the selected variable. If the variable is defined as a probability distribution or sequence, it opens the function in the Object Finder (see “Object Finder dialog”); if the variable is an editable table (edit table, subtable, or probability table), it opens the Edit Table window (see “Viewing an array as an edit table”). Otherwise, an Attribute panel (see “The Attribute panel”) or an Object window (see “The Object window”) opens, depending on the Edit Attributes setting in the Preferences dialog box (see “Preferences dialog”). This button is grayed out if no variable is selected. The keyboard shortcut is Control+e or F6.

Edit buttons

These three buttons control your mode of interaction with Analytica. The shape of the cursor reflects which mode you are in:

- **Browse tool:** Lets you navigate a model, compute and view results, and change inputs. It will not let you change other variables. See “Browse mode”.
- **Edit tool:** Lets you create new objects, and move and edit existing objects. See “Creating and editing nodes”.

Chapter 1  Examining a Model

The toolbar
Browsing with input and output nodes

When you open a model with input and output nodes, the top-level Diagram window may look like this (instead of an influence diagram):

You can change the values in the input nodes directly. The output node, Net present value, shows a Calc button. Click it to compute and see its value. Double-click the Model details node to open up a diagram showing details of the model (the influence diagram shown above).

Browse mode

An existing model opens in browse mode. In browse mode, the browse tool button is highlighted in the navigation toolbar, and the cursor looks like this ▶️. In the browse mode, you can change input node values, view output node results, and examine the model by opening windows to see more detail.

Viewing input nodes

An input field lets you see a single number or text value. Click in the box to edit the value. If it's a text value, you must put matching quotes around it (single or double).
Chapter 1

Examining a Model

The Object window

A pulldown menu lets you choose from a menu of alternatives. Press the menu to see the alternatives.

Click the button to open a list of values, usually defining an Index. To change a value, click in its cell. For more about lists, see “Editing a list”.

Click to open an edit table showing an editable array with one or more dimensions displayed as a table. For more, see “Editing a table”.

Click to view and edit a probability distribution in the Function Finder. For more, see “Probabilistic calculation”.

Viewing output node values

Click the Calc button to compute and display the value of this output variable. When computing is complete, it will show a number in this node, or, if it’s an array, it changes to the Result button and opens a Result window showing a table or graph. See Chapter 2, “Result Tables and Graphs” for more.

The Result button shows that an array has been calculated. Click it to open a Result window showing a table or graph. See Chapter 2, “Result Tables and Graphs” for more.

Opening module details

To see the structure of the model, double-click the module Model details, to display its diagram window (see “The Object window”).

The Object window

The Object window shows the attributes of an object. All objects have a class and identifier — a unique name of up to 20 characters. A variable also has a title, units, description, definition, inputs, and outputs:

To open an Object window

Here are some ways to open the Object window for an object x:

1. Double-click an input or output to open its Object window
2. Class menu
3. Identifier
4. Expressions popup menu (see page 120)
5. Editable field
6. To open an Object window
The Attribute panel

The Attribute panel offers a handy way to rapidly explore the definitions, descriptions, or other attributes of the variables and other nodes in a Diagram window. You can open the panel below the diagram, and use it to view or edit any attribute of the node you select. It shows the same attributes that you can see in the Object window, and often several other attributes.

Click the key icon to open the Attribute panel. Here are things you can do in it:
• Select another node in the diagram to see the selected attribute of a different object.

• Click the background of the diagram to see the attributes of the parent module.

• Select another option from the Attribute menu to see a different attribute.

• To enter or edit the attribute value, make sure you are in edit mode, and click in the attribute panel, and start typing. (Not all attributes are user-editable.)

Different classes of objects have different sets of attributes:

If you try to see an attribute not defined for an object, it will show its description.

See the “Glossary” for descriptions of these attributes. To display other attributes or to add new attributes, see “Managing attributes”.

To close the Attribute panel, click the key icon again.

### Showing values in the Object window

When reviewing a model and trying to understand how it works, it is useful to show the value of a variable and its inputs in the object window. To switch on this option, select Show with Values from the Object menu. The Object window for a variable then shows the mid (deterministic) value of the variable and each of its inputs:
atom and array values

If a value has not yet been calculated, it shows a Calc button. Click to compute it. If the resulting value is an atom — a single number or text value, not an array — it shows the value in the Object window, as above. If the value is an array, it shows instead a Result button, which you can click to compute and display the array in a separate Result window.

For more about the Result window, see Chapter 2, “Result Tables and Graphs.”

Printing

To print the contents of an active window — Diagram, Outline, Object, Result Table or Graph — select Print from the File menu. Selecting Print Setup on the File menu can then set printing options such as page orientation, paper size, or scaling. Any print settings that you specify are associated only with the window that was active when you selected Print Setup.

Previewing page breaks before printing

When you select the Print preview command on the File menu, it displays a Preview window to show what will be printed and where page breaks will occur. You can adjust print settings such as scaling until you get the desired page breaks. When previewing a result table or graph, you can toggle the option for showing or hiding the index variable titles.

When viewing a diagram, outline, or Object window, page breaks can be viewed while working by enabling Show Page Breaks on the Window menu.

Scaling printouts

You can adjust the magnification of your printouts using the Print Setup command on the File menu, or by using the Setup button on the Print Preview window, in two ways:

- Adjust to p % of normal size: p<100% to shrink output. p>100% to enlarge it.
- Fit to n page(s) wide by m page(s) tall: Shrinks the output to fit on the specified pages. It preserves aspect ratio. It does not enlarge, so the actual number of pages printed may be less than n x m.
Printing the background

There is a check box on the Print Setup window for controlling whether a diagram’s background color is printed. By not printing the background color, one can save on ink or toner. Whether the background is printed or not is controlled by the Print influence diagram background color check box. By default, it does not print the background.

Printing multiple windows

To print the contents of several windows into a single document, use the Print Report command in the File menu. It uses the print settings set in Print settings for each window.

Check Print outline (all objects) to print a list of all objects in the model, each in its parent module, indented to show the module hierarchy.

Check Print outline (modules only) to print a list of all modules (including libraries and form nodes), indented to show the module hierarchy.
This chapter shows you how to:

- View Result windows as graphs or tables
- Rearrange or pivot results, exchanging rows and columns, or graph axes and keys, and slicer dimensions.
- Select an uncertainty view to display probabilistic results.
- Compare two or more variables in the same table or graph.
The result window

When you open the Result window for a variable, it computes its value if it hasn’t previously cached it, and displays it. If the value is an array or a probability distribution, you can display it as a table or graph. Here is a Result window with a table and equivalent graph:

To open a result window
Click the variable node in its influence diagram to select it, and do one of these:
- Click the Result button in the toolbar, or press key Control+r.
- Select Show Result from the Result menu.
- Select an uncertainty view option, such as Mid Value, Mean Value, or Cumulative probability, from the Result menu.
- In the Attribute panel below a diagram, select Value or Probvalue from the Attribute menu, and click the Calc or Result button.

To open a Result window for an output node, simply click its Calc or Result button.

Result controls
The Result controls, in the upper left corner of the Result window include:

- Press the Uncertainty View popup menu, to select how to display an uncertain quantity. See “Uncertainty views”.
- Click this button to display the result as a table.
- Click this button to display the result as a graph.
Chapter 2  Result Tables and Graphs

The result window

Toggle between the table and graph views using the **Table View** and **Graph View** buttons.

**Index selection**

The **Index selection** area is the top part of a Result window. For a table, it shows which index goes down the rows, and which across the columns. For a graph, it shows which index is on the X axis (and sometimes Y axis) and which is in the key. For either view, if the array has too many dimensions to display directly, it also shows **slicers** that select the values of the extra indexes. Each control has a popup menu to let you exchange indexes and rearrange (pivot) the view:

The index selection area of a graph or table contains these items (example variables and indexes in the following text refer to the figure above):

**Title**  Shows the uncertainty view (Mid, Mean, etc.), the title of the variable, and its units, e.g., **Mid Value of Costs of buying and renting ($)**.

**Slicer index**  The title, units, and value of any index(es) showing dimensions not currently displayed in the table or graph.

**Slicer menu**  Press for a popup menu from which you can change the slicer value for the results displayed.

**Slicer stepper arrows**  Click or to cycle up or down through the slicer values.

**Row or key index**  Shows the title of the index displayed down rows for a table, or in the color key for a graph. Press to open a menu from which you can select another index:

**Column or X axis index**  Shows the title of the index displayed across the columns for a table, or along the X (horizontal) axis for a graph. Press to open a menu from which you can select another index.

**XY button**  Click to be able to plot this variable against one or more other variables, or to plot one slice of this variable against another slice. See “XY comparison” on page 105.

**Totals check boxes**  Check a box to show row or column totals the table view. If you check Totals for an index and then pivot it to be a slicer index, "Totals" will be its default slicer value. This lets you show total values over the slicer index in the graph or table.
The default view

When you first display a result for a variable, by default, it displays it as graph, if possible, and otherwise as a table. You can change this default in the Default result view in the Preferences dialog box (see "Preferences dialog").

When you display the Result window again, it uses all the options you last selected when you viewed this variable, including table versus graph, uncertainty view, index pivoting and slicer values, and any graph settings.

Recomputing results

If you change a predecessor of a variable shown in a Result window, the table or graph disappears from the window and is replaced by a Calculate button.

Click Calculate to compute and display the new value.

Viewing a result as a table

Toggle to table view If a result window shows a graph, click on the top left to toggle to table view.

The index display options depend on the number of dimensions in the variable.

Row index (down) Use this menu to select which index to display down the rows of the table. Select blank to display a single row.

Column index Use this menu to select which index to display across the columns of the table. Select blank to display a single column.

Slicer index(es) If the array has more than two indexes, the extra index(es) are shown as Slicer menus. The table shows values only for the slice (subarray) setting the slice index to the shown slicer value. Open the slicer menu to select a different slicer value, or click or to step through the slicer values.

Formatting numbers To specify the format for the numbers in a table or along the Y (usually vertical) axis of a graph, show the graph and select Number Format from the Result menu, or press
Chapter 2  Result Tables and Graphs  Viewing a result as a graph

Control-b. The **Number format** dialog offers many options, including currency signs, dates and Booleans. See “Number formats” for details.

### Viewing a result as a graph

**Toggle to graph view**  If a result window shows a table, click on the top left to toggle to graph view.

The **y axis**, usually vertical, plots the values of the variable. The **x axis**, usually horizontal, shows the value of a selected index. The index display options depend on the number of dimensions in the variable:

**X axis**  If the array has more than one index, use this menu to select which index to display along the x axis (usually horizontally).

**Key index**  If the array has more than one index, use this menu to select which index to display in the key, usually showing each value by color.

**Slicer index(es)**  If the array has more indexes than you can assign graphing roles (such as x axis or key), the extra indexes are shown as Slicer menus, as in a table view. The graph shows values only for the slice (subarray) setting the slice index to the shown slicer value. Open the slicer menu select a different slicer value, or click or to step through the slicer values.

**To reorder slicers**  If the graph has more than one slicer index, you can reorder the slicer indexes simply by dragging one up or down.

**Graph setup options**  There are a rich variety of ways to customize the graph, including line style (lines, data points, symbols, barcharts, stacked bars, thickness, transparency), axis ranges, log or
inverted axes, grid and tickmarks, background colors, and font color and size. To change these settings, open the **Graph Setup** dialog:

- Select **Graph Setup** from the **Result** menu, or
- Double-click anywhere on a graph in the **Result** window.

See “Graph setup dialog box” for details.

## Uncertainty views

Every variable has a certain or deterministic value, which we term its **mid** value. Some variables, notably **chance** variables and variables that depend on chance variables, may also have an **uncertain** (probabilistic) value, which we term a **prob** value. A mid value is computed using the mid value of each variable it depends on or the median of any probability distribution. The mid value of a result is not necessarily the median of its probability distribution, but usually close.

The **Result** window offers a Mid value and six **uncertainty views** as a way to visualize a prob value. You can select the uncertainty views from a menu in the top-left corner of a **Result** window. Or you may select a variable, and select an uncertainty view option from the **Result** menu:

The check mark indicates the currently selected view.

Here we illustrate each uncertainty view using the chance variable, **Rate_of_inflation**, defined as a normal distribution with a mean of 2.5 and a standard deviation of 1:

\[
\text{Chance Rate_of_inflation := Normal}(2.5, 1)
\]

### Mid value

The deterministic value, computed by using the median instead of any input probability distribution. It is computed very quickly compared to uncertain values. It is the only option available for a variable that is not probabilistic:
Tip  A mid value is much faster to compute than a prob(abilistic) value, since it doesn’t use Monte Carlo simulation to compute a probabilistic sample. It is often useful to look first at the mid value of a variable as a quick sanity check. Then you might select an uncertainty view, which will cause its prob value to be computed if it has not already been cached.

Mean value  An estimate of the mean (or expected value) of the uncertain value, based on the random (Monte Carlo) sample.

Statistics  A table of statistics of the uncertain value, usually, the minimum, median, mean, maximum, and standard deviation, estimated from the random sample. You can select which statistics to show in the Statistics tab of the Uncertainty Setup dialog from the Result menu (see “Statistics option”).
Probability bands  An array of percentiles (fractiles) estimated from the random sample, by default the 5%, 25%, 50%, 75%, and 95%iles. You can select which percentiles to show in the Probability bands tab of the Uncertainty Setup dialog from the Result menu (see “Statistics option”).

![Probability bands example](image)

Probability density  Select probability density to display the uncertain distribution as a probability density function (PDF).

For a probability density function, it plots values of the quantity over the X (usually horizontal) axis, and probability density on the Y (vertical axis). Probability density shows the relative probability of different values. High values show probable regions; low values show less probable regions. The peak is the mode, the most probable value. If the density is zero, it is certain that the quantity will not have values in that range.

![Probability density example](image)

Probability mass function  If you select Probability density for a discrete variable, it actually displays the variable as a probability mass function (PMF) in a bar graph with the height of each bar indicating the probability of that value:
Chapter 2  Result Tables and Graphs  Uncertainty views

Usually, it figures out whether to use a probability density or mass function. Very rarely, you may need to tell it the domain is discrete. See “The domain attribute and discrete variables”. See “Is the quantity discrete or continuous?” and “Probability density and mass graphs” for more about the distinction between discrete and continuous distributions.

**Cumulative probability**

The cumulative probability distribution (CDF) plots the possible values of the uncertain quantity along the X (usually horizontal) axis. The Y value (usually height) of the graph at each value of X shows the probability that the quantity will be less than or equal to that x value. The CDF must start at a probability of 0 on the extreme left and increase to a probability of 1 on the extreme right, never decreasing.

The steeper the curve, the more likely the quantity will have a value in that region. The PDF is the slope (first derivative) of the CDF. Conversely, the CDF is the cumulative integral of the PDF.

**Sample**

A sample is an array of the random values from the distribution generated by the Monte Carlo sampling process. The sample is the underlying form used to represent each
Comparing results

It’s easy to compare directly two or more variables in one table or graph:

1. Select the variables together in the diagram, using Shift+click to add each to the selection, or dragging a selection rectangle around them:
2. Click \(\text{COMPARE} \) in the navigation toolbar, or press Control+r.

3. Click OK in the confirmation dialog.

This creates a new variable with a default identifier, compare1, with a list of the selected variables:
The result of \texttt{Compare1} is a graph containing an index containing the titles of the variables being compared. This index is Self index of the \texttt{Compare1}. It also includes all the indexes of the array variables being compared — in this case, \texttt{Time} and \texttt{Buying Price}:

![Compare1 Graph](image)

This helps clarify how the interest payments reduce (become less negative) as the principal payments on the mortgage increase (become more negative).
This chapter shows you how to perform a parametric analysis on a model by:

- Selecting variables as parameters
- Specifying alternative values for the parameters
- Examining the results
A potent source of insight into a model is examining the behavior of its outputs as you systematically vary one or more of its inputs. This technique is called **model behavior analysis**. Each input that you vary systematically is called a **parameter**, and so this technique is also known as **parametric analysis**. Analytica makes it simple to analyze model behavior in this way. All you have to do is to assign a list of alternative values to selected input parameter. When you view the result of any output, Analytica computes and displays a table or graph showing how the output values vary for all combinations of the input values.

This chapter describes how to select variables as parameters, how to specify alternative values for the parameters, and how to examine the results.

### Varying input parameters

The first step in analyzing model behavior is to select one or more input variables as parameters and to assign each parameter a list of possible values.

**Which inputs to vary?** You can vary any numerical input variable of your model, including decision and chance variables. Often you will want to vary each decision variable to see which value gives the best results according to the objectives. You may also want to vary some chance variables to see how they affect the results. It is often best to look first at the decision or chance variables that you expect to have the largest effect on the model outputs. In complicated models, you may want to start with an importance analysis, to identify which chance variables are likely to be most important. (See Chapter 16, “Statistics, Sensitivity, and Uncertainty Analysis”.) You can then select the most important variables as the parameters to vary to analyze model behavior.

**How many values to assign?** Usually it is best to assign a list of three alternative values to each parameter — a low, medium, and high value. In some cases, two values may be sufficient. If you have a special interest in a particular parameter (for example, if you suspect it may have a strongly nonlinear effect) you may want to assign more than three values to examine in more detail the model behavior as the parameter varies. Naturally, the computation time increases with the number of values.

**Creating a list** Change the definition of each parameter to a list, thus:

1. Select the variable by clicking its node in the influence diagram.
2. Display the variable’s definition by clicking the **Definition** button in the tools palette, or press Control+e.
3. Click the **Expressions** popup menu above the definition and select the **List** option. (Do not select the **List of Labels** option.)
4. A dialog box asks for confirmation. Click **OK**.

It displays a list with one item, containing the old definition of the variable.

5. Click the item to select it.

6. Type in the lowest value for the variable.

7. Press **Enter** and type in the next value.

8. Repeat step 7 until you have all the values you want.

**Tip**  
When you add an item to a list of two or more numbers, it uses the increment between the last two numbers to generate the next. If the last two values are 10 and 20, it offers 30 as the next.

For details on how to edit a list, see "Editing a list" on page 165.

If you want to create a list of successive integers, use the ".." operator, for example:

```
Decision Year := 2000 .. 2010
```

If you want to create a list of evenly spaced numbers, use the `Sequence(x1, x2, dx)` function, for example:

```
```

See “Sequence (start, end, stepSize)” on page 166.

**How many inputs to vary**  
Typically you should start a model behavior analysis by varying just one input variable, the one you expect to be most important. Vary additional variables one at a time, in order of their expected importance. If a variable turns out to have little effect, you may restore it to its original value or probability distribution. If you have many inputs whose
effects on model behavior you would like to explore, vary just a few at a time, rather than trying to vary them all simultaneously.

Each parameter that you vary becomes a new dimension of your output result array. The computation time and memory needed increase roughly exponentially as you add parameters. Moreover, you may find it hard to interpret an array with more than three or four dimensions. Remember that the goal is to obtain insight into what affects the model behavior and how.

Analyzing model behavior results

Once you have assigned a list to one or more inputs, you can examine their effect by viewing the result on an output variable. If your model has an objective, you might start by looking at that variable.

1. Select the variable you wish to view by clicking its node in the diagram.
2. View the result by clicking the Result button in the navigation toolbar. The result displays as a table or graph.

The result is an array with a dimension for each input parameter that you have varied (in this example, Buying price and Appreciation rate). If an input parameter does not appear as a dimension of the result, it implies that the result variable does not depend on the input. The result may also have other dimensions that are not input parameters you have varied — for example, Time for a dynamic model.

It is generally easiest to look first at the result graph to see the model’s general behavior. You need to look only at the result table if you want to see the precise numerical values. If you are varying more than one input parameter, try rearranging the dimensions (see “Index selection”) to get additional insights into model behavior.
Chapter 3  Analyzing Model Behavior

Analyzing model behavior results

**Understanding unexpected behavior**

If you find the model’s behavior unexpected or inexplicable, you may want to look more deeply into how the behavior arises. An easy way to do this is simply to look at the results for other variables between the input(s) and the output(s) in which you’re interested. You can work forwards from an input towards the output, or backwards from the output towards the inputs. Look at the behavior of each intermediate variable, and see if you can understand why the inputs affect it the way they do.

Typically, the reason for unexpected behavior will quickly become clear to you. It may be that some intermediate relationship has an effect different from what you expected. It may turn out that there is an error in a definition. In either case, this kind of exploration can be very revealing about the model. You may end up improving the model or gaining a deeper understanding of the system it represents.

**Understanding model behavior**

By examining result graphs, you can learn if each input affects the output, if the effect is linear or non-linear, and if there are interactions among inputs in their effect on the output. Below are some typical graph patterns and their qualitative interpretations.

- A horizontal line shows that changes in the input over the specified range have no effect on the output.
• A straight line shows that the output depends linearly on the input — provided that you have specified more than two different values for the input.

• A bent or curved line shows that there is a nonlinear dependence. (If you have only two values for the input, the graph will be a straight line even if there is a nonlinear dependence.)
Creating and Editing a Model

This chapter shows you how to:

• Create a new model
• Save changes
• Create and edit nodes
• Draw arrow connections between nodes
• Create aliases
Creating and saving a model

To start a new model

Start Analytica like any Windows application: Select **Analytica** from the Windows **Start** menu or double-click the Analytica application file. It opens a new, untitled model.

If you are already running an Analytica model, you can also select **New Model** from the **File** menu. Since once instance of Analytica can’t run two models at once, it first prompts you to save the existing model, if you have changed it.

The model **Object** window shows information about the model, such as the author(s), and creation and save dates; it also includes space for a description of the model’s purpose.

When you start a new model, it displays the **Object** window for the new model, initially **untitled**. First, enter a title, description, and possible name yourself in the Author attribute:

When you have entered a title and other attributes into the **Model object** window, bring the **Diagram** window to the top:

- Click the **Parent Diagram** button, or
- Click anywhere in the **Diagram** window behind the **Object** window.

You are now ready to draw an influence diagram for the new model.

Creating and editing nodes

To begin editing a diagram, if you are not already in edit mode, click the edit tool. This displays the **node toolbar** as an extension of the navigation toolbar:
Creating and Editing a Model

Chapter 4

Creating and editing nodes

For a description of each node shape (or class), see “Classes of variables and other objects”.

Create a node

To create a new node, press the node class you want in the node toolbar and drag it to the location you want in the diagram. You can then type a title into the new node.

Edit a node title

To edit the title of a node (in edit mode) click it once to select the node; then click its title. (Pause momentarily between mouse clicks to prevent them being interpreted as a double-click, which would open the node’s Object window.) Then type in a new title to replace the old one. Or click a third time to put a cursor into the existing title where you can add text.

Click a node once to selects it, showing its handles — small black squares at its corners:

- The edit tool is highlighted to show that it is selected.
- The node toolbar is displayed when either the edit tool or arrow tool is selected.
After editing the title, click outside the node (or press Tab or Alt-Enter) to accept the new title. If the node is too small for the title text, it expands the node vertically to fit. It can accept a title of up to 128 characters, but it’s usually best not to have titles longer than about 40 characters.

Identifiers and titles

Every node has a unique identifier of up to 20 characters. Formulas in the definition of a variable or function refer to other variables or functions by their identifier. The title is usually longer. It is used for node labels in the diagram and other places for your convenience as the model builder or end user.

By default, when you create a node, it forms an identifier for the node from its title, consisting of the first 20 characters of the title, using underscore '_' to replace any character that is not a letter or number. If the first character is not a letter, it substitutes ‘A’, because identifiers must start with a letter.

Identifiers must be unique, unlike titles. So, if by chance there already exists an object with the same identifier, it will append a number to the new identifier to keep it unique.

If you want, you can edit an identifier directly in the Object window or attribute panel, like any other user-editable attribute.

If you edit the title again, by default, it will ask if you want to change the identifier to match the new title. Usually, it’s simplest to have them match. But, sometimes you may want to retain the original identifier. You can switch off this default behavior by unchecking Change identifier when title changes in the Preferences dialog from the Edit menu. (See “Change identifier”).

When you, or Analytica, change an identifier, it automatically updates any definitions that refer to it to use the new version, to keep the model consistent.

Select a node

To select a node, single-click it. Handles indicate that you have selected the node. To deselect a selected node, click anywhere outside of it.

To select or deselect multiple nodes, press and hold the Shift key while selecting the nodes. You can also select a group of nodes by dragging a rectangle around them. Move the cursor to a corner of the diagram (not in a node), press the mouse button, and drag the mouse to draw a rectangle. When you release the button, all the nodes completely inside the rectangle are selected.

Move a node

To move a node, click the mouse in the node (not on a handle), and drag the node to where you want it.

You can also adjust node positions using the arrow keys (up, down, left, right). By default, each arrow press moves the node by 8 pixels. If you uncheck Snap-to-grid in the Diagram menu, each arrow press moves it by a single pixel.

Move a node to another module

Simply drag the node onto the module until the module becomes highlighted. When you release the mouse button, the node moves into the module. It will have the same location in the diagram of the new module that it previously had in the old one.

Alternatively, double-click the module to open its diagram window. Move the diagram windows so both you can see both the node and the new diagram. Then drag the node to the desired location in the new diagram.
Chapter 4  Creating and Editing a Model

Drawing arrows

Use the arrow tool to draw or remove arrows (influences) between variable nodes. Drawing an arrow from variable or function \( a \) to \( b \) puts \( a \) in the list of inputs of \( b \). This makes it conveniently available to select from the inputs menu when creating or editing the definition of \( b \) (see "Creating and Editing Definitions").

**Draw an arrow**

To draw an arrow, first click the arrow icon \( \rightarrow \) in the toolbar to select the arrow tool. In arrow mode, the cursor changes to this arrow icon when over a diagram window.

1. Drag from the origin node (which highlights) to the destination node (which also highlights).
2. Release the mouse button, and it draws the arrow.

To speed up drawing arrows from multiple nodes to a single destination, select all the origin nodes. Then drag from any origin node to the destination node. When you release the mouse, it draws arrows from all the origin nodes.

### Change the size of a node

Click the node to show its handles. Then drag a handle until the node is the size you desire. By default, it fixes the center of the node at the same location, and expands or contracts its four corners. This keeps node centers aligned with the grid. If you want to move one corner, leaving the opposite corner fixed, uncheck **Resize Centered** in the **Diagram** menu.

### Delete a node

Select the node(s) and choose **Clear** from the **Edit** menu, or press the **Delete** key. It will ask you to confirm your intention because deleting cannot be undone. Sometimes it is better to create a module and title it Trash. (There is a Trash library with a suitable icon.) Then you can drag nodes into it — and still retrieve them just in case.

### Cut, copy and paste nodes

You can use the standard **Cut** (Control+x), **Copy** (Control+c), and **Paste** (Control+v) commands from the **Edit** menu on one or a collection of nodes. Initially, the copies are identical except it appends a number to the identifiers to make them unique.

If you cut a node, you can paste it just once. If you copy a node you can paste it as many times as you wish.

### Duplicate nodes

Select the node(s) and choose **Duplicate Nodes** from the **Edit** menu (or press Control+d). This is equivalent to using **Copy** and **Paste**, without writing to the clipboard. Duplicating a node creates a new object identical to the original, adding a number to its identifier to make it unique and located below and to the right.

Duplicating a set of nodes retains the same relationships among the duplicated nodes as exists among the origin nodes. For example, suppose you have three variables:

- \( \text{Variable } X := 100 \)
- \( \text{Variable } Y := X^2 \)
- \( \text{Variable } Z := X + Y \)

If you duplicate \( Y \) and \( Z \), but not \( X \), you will get two new variables:

- \( \text{Variable } Y_1 := X^2 \)
- \( \text{Variable } Z_1 := X + Y_1 \)

Note that it appends “1” to the identifiers to make them distinct from their original nodes. And that the definition of \( z_1 \) refers to the unduplicated \( X \) and the duplicated variable \( Y_1 \).
Tip

Some arrows are hidden. They do not appear even when you try to draw them. For example, by default arrows to and from indexes and functions are not shown. See “Diagram Style dialog” on page 81 and “Node Style dialog” on page 82 to change these settings.

To remove an arrow

- Click the arrow to select it, then press the Backspace or Delete key, or
- Just redraw the arrow from the origin node to the destination node. If the origin variable is used in the definition of the destination, it will ask if you really want to remove it.

Tip

When you enter or edit a definition, Analytica automatically updates the arrows into the variable to reflect those other variables that it mentions (or does not mention). See “Creating or editing a definition”.

Influence cycle or loop

An influence cycle occurs when a variable A depends on itself directly, where \( A \rightarrow A \), or indirectly so that the arrows form a directed circular path, e.g., \( A \rightarrow B \rightarrow C \rightarrow A \).

If you try to draw arrows that would make a cycle, it will warn and prevent you. The exception is if at least one of the variables in the cycle is defined with the Dynamic function, and contains a time-lagged dependence on another variable in the cycle, shown as a gray arrow (see Chapter 17, “Dynamic Simulation”).

Arrows linking to module nodes

When there are arrow between variables in different modules, they are reflected by arrows to and from the module nodes:
How to draw arrows between different modules

You may draw arrows between variables in different modules, either directly (if both diagram windows are visible on screen, or indirectly. Here are several methods. Suppose you want to draw an arrow from the variable **Buying price** to the variable **Mortgage loan amount** in another module:
How to draw arrows between different modules

1. Open the two Diagram windows and arrange them so that both origin and destination nodes are visible on screen at the same time.

2. In arrow mode, press on the origin node, Buying price, so that it highlights. Drag an arrow to the destination node, Mortgage loan amount, which also highlights. Release the button.

If, as in this case, the destination module appears in the origin diagram, the arrow points from the origin node Buying price to the destination module Cost to Buy; a small arrowhead appears on the left edge of destination node Mortgage loan amount showing that it has an input node from another diagram:

- **Move nodes to same diagram to link them**: A second method is to move one of the nodes into the diagram containing the other. Then you simply draw an arrow between them. Finally, you move the node back to the diagram it came from. This may be convenient if you have large diagrams and a small screen so that they are hard to arrange so that both nodes are visible in different diagrams.

- **Copy or type the origin into destination definition**: Copy the identifier of the origin variable, open the definition of the destination variable, and paste it in. (See “Creating or editing a definition”). When the definition is complete and accepted, it will automatically draw the arrows to reflect the relationships.

- **Make an alias node in the other diagram**: If the origin node and destination module are in the same diagram, you can draw an arrow directly between them. This will make an alias node of the origin in the destination diagram.
Character Reading and Editing a Model

Chapter 4

Creating and Editing a Model

Alias nodes

An alias is a copy of a node, referring to the same variable, module, or other object as the original node. It’s often useful to display an alias node in a different module than its original node. For example, if module \( M_1 \) contains variable \( x \) and its inputs, and \( x \) has outputs in another module \( M_2 \), it is often useful to add an alias of \( x \) in \( M_2 \) to display the influence of \( x \) on its outputs explicitly. This makes it easy to draw arrows from \( x \) to or from other variables in \( M_2 \).

A variable or other object may have only one original node, but an unlimited number of alias nodes.

Tip

An alias node is identified by its title being shown in italics.

You can create an alias directly with the Make alias command, or indirectly by drawing an arrow to or from a module node:

**Make Alias command**

Select the original node. Then choose the Make Alias option from the Object menu (or press Control+m). The alias node appears next to the original node. You can then drag it into another module.

**Draw arrow between variable and module**

Draw an arrow from the original node to a module node, or from a module node to the original node. This creates an alias in the module. For example, draw an arrow from the variable Buying price to the module Cost to Buy:

It displays an arrow between the nodes:
Open up the module **Cost to Buy** to see the new alias:

![Diagram - Cost to Buy](image1)

**Draw arrow between two modules**
If you draw an arrow from one module node **Cost to Buy** to another module **Total Cost**, it creates a new variable node with a default name, such as **Va1**, in the first module **Cost to Buy**, with an alias of **Va1** in the second module **Total Cost**.

![Diagram - Cost to Buy](image2) ![Diagram - Total Cost](image3)

**An alias is like its original**
An alias looks and behaves like its original node, except the fact that its label is in *italics*: You can select it, double-click it to open its **Object** window, move, resize, edit its label, and draw arrows to or from it, just like any other node. The alias and original show the same title: If you edit the title in one of them, it automatically changes in the other.

**How alias and original can differ**
On the other hand, the properties of the *node* — rather than the *object* that it depicts — may differ between the original and its alias: You can modify one node’s location (obviously) and size, its color (using the Color palette), and its styles (see “Node Style dialog”).

**Tip**
If an alias and its original node are in the same diagram, it displays any arrows to or from only the *original* node, not the alias. If the alias is in a different module, it displays arrows connecting it to other nodes in that module, as they would be displayed if it were the original node.

**Input and output nodes are aliases**
Input and output nodes are kinds of alias nodes that have special node style properties. See “Using input nodes” page 128 and “Using output nodes”.

---

Chapter 4 Creating and Editing a Model

A **li**as **nodes**
To edit an attribute

You can edit most attributes of an object directly in the **Attribute** panel (see “The Attribute panel”) or in the **Object** window (see “The Object window”). User-editable attributes include identifier, title, description, units, and definition. See next section on how to change class. Some attributes you cannot edit because they are computed, including inputs, outputs, and value.

To edit an attribute, first display it in the Attribute panel or Object window for the object, and make sure you are in edit mode. Then:

1. Click in the **Attribute** field. A blinking text cursor and dotted outline around the attribute indicate that the attribute is editable.
2. Use standard text-editing methods to edit it: type, copy and paste, and use the mouse to select text or move the cursor.
3. To save the changes, click anywhere outside the **Attribute** field, press **Enter**, or display another attribute.

**Cancel and undo edits**

To cancel changes while editing an attribute, press the **Esc** (escape) key to revert to the previous version. Except when editing a definition, click **x** to cancel changes. To cancel changes **after** you have just made and accepted them, select **Undo** from the **Edit** menu (or press **Control+z**).

**Attribute changes**

All displays of an object use its same attributes: So any change to an attribute will affect all views that display that attribute. For example, any change to a title appears in other diagram nodes, object windows, or result views referring to that object by title. Any change to a definition will cause redrawing arrows to reflect any changes in dependencies.
To change the class of an object

You may press on the class of a variable or module in an object window or attribute panel to open a popup menu. The options depend on whether the node is a variable or a module:

To change class, just select another option from the menu. The shape of the node and other class-dependent properties will change automatically.

**Tip**

You cannot change the class of a function, and you cannot change a variable into a module, or vice versa.

For more, see “Classes of variables and other objects”.

**Module Subclasses**

All modules contain other objects, including sometimes other modules. There are several different subclasses of module:

- **Model**: is usually the top module in a module hierarchy, and is saved as a separate file (document with extension .ANA). Any nondefault preferences (see “Preferences dialog”), uncertainty options (see “Uncertainty Setup dialog box”), and graph style templates are saved with the model, but not other module types.

- **Module**: A collection of nodes that are displayed in a single diagram. A standard module contains a set of other nodes, and is usually part of the module hierarchy within a model or other module type.

- **Filed module**: A module whose contents are saved in a file separate from the model that contains it. A filed module can be shared among several models, without having to make a copy for each model. See “Using filed modules and libraries”.

- **Library**: A module that contains functions and sometimes variables. Read-in libraries are listed in the Definition menu below the built-in libraries, with a hierarchical sub-
Preferences dialog

Use the Preferences dialog to inspect and set a variety of preferences for the operation of Analytica. All preference settings are saved with the model. To open the Preferences dialog, select Preferences from the Edit menu.

Windows of each kind

Use the options in this box to control how many windows of various kinds are displayed at once (see “Managing windows”).

- **One only**: Check this box to close an existing window (if there is one) whenever you open a new window.
- **Any number**: Check this box to keep all windows open until you explicitly close them.
- **Result windows**: Enter a value in this field to indicate the number of Result windows that you can keep open simultaneously. The default (and minimum) number is 2; the maximum number is 20.

Change identifier

Use the options in this box to control the changing of identifiers. See “Creating and editing nodes” for a description of how identifiers are initially assigned.
Preferences dialog

When title changes
Check this box to change a variable’s identifier whenever you change its title. Analytica uses up to the number of specified characters (20 by default, range from 2 to 20), replacing spaces and returns with an underscore character (_), and omitting anything between parentheses.
If the box is not checked, the identifier is changed only when you explicitly edit it.

Ask before renaming
Check this box to see a confirmation dialog box before automatic changing of a variable’s identifier.

Opens
These radio buttons control where you view the definition of a selected object, when you click in the toolbar, press Control+e, or when you choose to edit a variable from a warning message:

Object window
Open the Object window and select the definition text (see “The Object window”).

Diagram Attribute panel
Open the Attribute panel on the appropriate Diagram window and select the definition text (see “The Attribute panel”).

Maintain Recovery Info
When this checkbox is checked (the default), Analytica saves each change to a recovery file, starting from the last point at which the model was saved. If the application terminates unexpectedly due to a software or hardware problem, the next time you start Analytica, it detects the recovery file and displays a dialog offering to resume the model where you left off, including all changes.

The only reason to switch off this option is when you are editing huge edit tables, in which case, this feature may slow down editing and consume significant disk space for the recovery file.

Unlike the other preference settings, this is stored as a user setting, and is not stored with the model.

Tip
Even when Maintain Recovery Info is checked, we recommend you save your model at frequent intervals.

Default result view
Select the radio button to specify which view you prefer as the default when you first display the Result window for a variable (see “The result window”).

Display result as a table.

Display result as a graph.

If you change the view in a result window, it will use that view next time you open that result.
## Chapter 4 Creating and Editing a Model

### Preferences dialog

</table>
| **Check Variable class** | - A variable whose class is not Chance contains a probability distribution.  
- A constant depends on another variable (other than indexes to an edit table).  
- An index has a value that is not a one-dimensional array, or is an array with another index. |
| **Check value bounds** | Evaluate check attributes for variables that have them. See “Automatic checking for valid values”. |
| **Show undefined nodes without a valid definition display with cross-hatching:** | Nodes without a valid definition display with cross-hatching: |
| **Flag nodes w/descriptions** | Show a red triangle in their upper right corner of nodes that have text in their description attribute: |
| **Show module hierarchy** | Show a hierarchy bar at the top of each Diagram window showing its nesting level. See “Show module hierarchy preference” |
| **Show result warnings** | If checked, it stops evaluation and shows a warning message, when it encounters a warning condition. If unchecked, it continues without displaying a warning. |
| **Use Return to enter data** | A standard MS Windows keyboard has a Return key located on the alphanumeric section of the keyboard, and a separate Enter key located on the numeric keyboard. When this checkbox is unchecked (the default), the return key starts a new line in a multi-lined text field (such as a definition) while the Enter key or Alt-Return signal that the data entry is complete. When checked, these are reversed, with Enter or Alt-Return starting a new line and Return completing the entry of data. |
| **Safe Intermediates** | Analytica ensures that all intermediate arrays generated during evaluation are fully rectangular. By default this is checked. If unchecked, some large models — especially those using dynamic simulation — run faster, sometimes dramatically so. Very occasionally, unchecking can cause incorrect results. If speed is an issue, compare results with this box checked and unchecked. If the values are the same, uncheck this checkbox to improve performance. |
| **Auto recompute outgoing OLE links** | Analytica automatically recomputes and updates OLE-linked tables whenever model changes affect them. With large models, it is sometimes best to uncheck this box to avoid immediate time-consuming recomputation after each small change. See OLE linking in “Using OLE to link results to other applications”. |
Chapter 5

Building Effective Models

This chapter shows you how to build models that are:

- Focused
- Simple
- Clear
- Comprehensible
- Correct
Creating useful models is a challenging activity, even for experienced modelers; effective use of influence diagrams can make the process substantially easier and clearer. This chapter provides tips and guidelines from master modelers (including Newton and Einstein) on how to build a model that is effective, one that focuses on what matters, and that is simple, clear, comprehensible, and correct. The key is to start simple and progressively refine and extend the model where tests of initial versions suggest it will be most important.

Most of the material in this chapter, unlike the other chapters in this guide, is not specific to Analytica. These guidelines are useful whether you are using Analytica, a spreadsheet, or any other modeling tool. However, Analytica makes it especially easy to follow these guidelines, using its hierarchical influence diagrams, uncertainty tools, and Intelligent Arrays.

These guidelines have been distilled from many years of experience by master modelers, using Analytica and a variety of other modeling software. However, they are general guidelines, not rules to be adhered to absolutely. We suggest you read this chapter early in your work with Analytica and revisit it from time to time as you gain experience.

**Creating a model**

Below are general guidelines to help you build models that provide the greatest value with the least effort.

**Identify the objectives**

What are the objectives of the decision maker? Sometimes the objective is simply to maximize expected monetary profit. More often there are a variety of other objectives, such as maximizing safety, convenience, reliability, social welfare, or environmental health, depending on the domain and the decision maker. Utility theory and multi-attribute decision analysis provide an array of methods to help structure and quantify objectives in the form of utility. Whatever approach you take, it is important to represent the objectives in an explicit and quantifiable form if the objectives are to be the basis for recommending one decision option over another.

It is a useful convention to put the objective variable or variables (hexagonal nodes) on the right of the diagram window, leaving space on the left side for the rest of the diagram.

![Diagram showing hexagonal nodes for objectives]

The most common mistake in specifying objectives is to select objectives that are too narrow, by concentrating on the most easily quantifiable objective — typically, near-term monetary costs — and to forget about the other, less tangible objectives. For example:
• When buying software you may want to consider the usability and reliability of different software packages, as well as long-term maintenance, not just cost and performance.

• In pricing a product, you may want to consider the long-term effects of increased market share in developing new customers and markets and not just short-term revenues.

• In selecting a medical treatment, you may want to consider the quality of life if you survive the treatment, and not just the probability of survival.

For an excellent guide on how to identify and structure objectives, see *Value-Focused Thinking* by Ralph Keeney (Appendix G., “Bibliography”).

**Identify the decisions**

The purpose of modeling is usually to help you (or your colleagues, organization, or clients) discover which decision options will best meet your (or their) objectives. You should aim, therefore, to include the decisions and objectives explicitly in your model.

A **decision variable** is one that the decision maker can affect directly — which computer to buy, how much to bid on the contract, which medical treatment to choose, when to start construction, and so on. Occasionally, people want to build a model just for the sake of furthering understanding, without explicitly considering any decisions. Most often, however, the ultimate purpose is to make a better decision. In those cases, the decision variables are where you should start your model.

When starting a new influence diagram, put the decision variables — as rectangular nodes — on the left of the diagram window, leaving space for the rest of the influence diagram to the right.

**Link the decisions to the objectives**

The decisions and objectives are the starting and ending points of your model. Once you have identified them, you have reduced the diagram construction to the process of creating the links between the decisions and objectives, via intermediate variables. You may wish to work forward from the decisions, or backward from the objectives. Some people find it easiest to alternate, working inward from the left and the right until they can link everything up in the middle.
Creating a model

It helps to identify the decisions and objectives early during model construction, to maintain focus on what matters. There may be a bewildering variety of variables in the situation that may seem to be of potential relevance, but, you only need to worry about variables that influence how the decisions might affect the objectives. You can ignore any variable that has no effect on the objectives.

Focus on identifying the variables that make clear distinctions — variables whose interpretations won’t change with time or viewer. Extra effort here will be repaid in model accuracy and cogency.

An influence diagram is a purely qualitative representation of a model. It shows the variables and their dependencies. It is usually best to create most or all of the first version of your model just as an influence diagram, or hierarchy of diagrams, before trying to quantify the values and relationships between the variables. In this way, you can concentrate on the essential qualitative issues of what variables to include, before having to worry about the details of how to quantify the relationships.

When the model is intended to reflect the views and knowledge of a group of people, it is especially valuable to start by drawing up influence diagrams as a group. A small group can sit around the computer screen; for a larger group, it is best if you have the means to project the image onto a large screen, so that the entire group can see and comment on the diagram as they create it. The ability to focus on the qualitative structure initially lets you involve early in the process participants who might not have the time or interest to be involved in the detailed quantitative analysis. With this approach, you can often obtain valuable insights and early buy-in to the modeling process from key people who would not otherwise be available.

Perhaps the most common mistake in modeling is to try to build a model that is too complicated or that is complicated in the wrong ways. Just because the situation you are modeling is complicated doesn’t necessarily mean your model should be complicated. Every model is unavoidably a simplification of reality; otherwise it would not be a model. The question is not whether your model should be a simplification, but rather how simple it should be. A large model requires more effort to build, takes longer to execute, is harder to test, and is more difficult to understand than a smaller model. And it may not be more accurate.

“A theory should be as simple as possible, but no simpler.” Albert Einstein

Building a new model from scratch can be a challenge. If you can find an existing model for a problem similar to the one you are now facing, it is usually much easier to start with the existing model and adapt it to the new application. In some cases, you may find parts or modules of existing models that you can extract and combine to address a new problem.
To find a suitable model to adapt, you can start by looking through the example models distributed with Analytica. If there is an Analytica users’ group in your own organization, it may collect a model library of classes of problems of interest to your organization. You can also check the Lumina wiki for Analytica libraries, templates, and example models (http://lumina.com/wiki).

“If I have seen further than [others] it is by standing upon the shoulders of Giants.” Sir Isaac Newton

Aim for clarity and insight
The goal of building a model is to obtain clarity about the situation, about which decision options will best further your objectives, and why. If you are already clear about what decision to make, you don’t need to build a model, unless, perhaps, you are trying to clarify the situation and explain the recommended decisions for others. Either way, your goal is greater clarity. This goal is another reason to aim for simplicity. Large and complicated models are harder to understand and explain.

Testing and debugging a model

Even with Analytica, it is rare to create the first draft of a model without mistakes. For example, on your first try, definitions may not express what you really intended, or may not apply to all conditions. It is important to test and evaluate your model to make sure it expresses what you have in mind. Analytica is designed specifically to make it as easy as possible to scrutinize model structures and dependencies, to explore model implications and behaviors, and to understand the reasons for them. Accordingly, it is relatively easy to debug models once you have identified potential problems.

Test as you build
With Analytica, you can evaluate any variable once you have provided a definition for the variable and all the variables on which it depends, even if many other variables in the model remain to be defined. We recommend that you evaluate each variable as soon as you can, immediately after you have provided definitions for the relevant parts of the model. In this way, you’ll discover problems as soon as possible after specifying the definitions that may have caused them. You can then try to identify the cause and fix the problem while the definitions are still fresh in your memory. Moreover, you’ll be less likely to repeat the mistake in other parts of the model.

If you wait until you believe you have completed the model before testing it, it may contain several errors that interact in confusing ways. Then you’ll have to search through much larger sections of the model to track them down. But if you have already tested the model components independently, you’ll have already removed most of the errors, and it will usually be much easier to track down any that remain.

Test the model against reality
The best way to check that your model is well-specified is to compare its predictions against past empirical observations. For example, if you’re trying to predict future changes in the composition of acid rain, you should try to compare its “predictions” for past years for which you have empirical observations. Or, if you’re trying to forecast the future profitability of an existing enterprise, you should first calibrate your model for past years for which accounting data are available.

Test the model against other models
Often you don’t have the luxury of empirical measurements or data for the system of interest. In some cases, you’re building a new model to replace an old model that is out-of-date, too limited, or not probabilistic. In these cases, it is usually wise to start by reimplementing a version of the old model, before updating and extending it. You can then compare the new model against the old one to check for discrepancies. Of course, differences may be due to errors in the new model or the old model. Once you have
resolved any discrepancies, you can be confident that you are building on a foundation that you understand.

If the model is hard to test against reality in advance of using it, and if the consequences of mistakes could be catastrophic, you can borrow a technique that NASA uses widely for the space program. You can get two independent modelers (or two modeling teams) each to build their own model, and then check the models against each other. It is important that the modelers be independent, and not discuss their work ahead of time, to reduce the chance that they will both make the same mistake. For a sponsor of models for critical applications in public or private policy, this multiple model approach can be very effective and insightful. The competition keeps the modelers on their toes. Comparing the models’ structure and behavior often leads to valuable insights.

Have other people review your model

It’s often very helpful to have outside reviewers scrutinize your model. Experts with different views and experiences may have valuable comments and suggestions for improving it. One of the advantages of using Analytica over conventional modeling environments is that it’s usually possible for an expert in the domain to review the model directly, without additional paper documentation. The reviewer can scrutinize the diagrams, the variables, their definitions and descriptions, and the behavior of the model electronically. You can share models electronically on diskette, over a network, or by electronic mail.

Test model behavior and sensitivities

Many problems become immediately obvious when you look at a result — for example, if it has the wrong sign, the wrong order of magnitude, or the wrong dimensions, or if Analytica reports an evaluation error. Other problems, of course, are not immediately obvious — for example, if the value is wrong by only a few percentage points. For more thorough testing, it is often helpful to analyze the model behavior by specifying a list of alternative values for one or two key inputs (see Chapter 3, “Analyzing Model Behavior”), and to perform sensitivity analysis (see Chapter 16, “Statistics, Sensitivity, and Uncertainty Analysis”). If the model behaves in an unexpected way, this may be a sign of some mistake in the specification. For example, suppose that you are planning to borrow money to buy a new computer, and the net value increases with the interest rate on the loan; you might suspect a problem in the model.

Celebrate and learn from unexpected behavior

If analyzing the behavior or sensitivities of your model creates unexpected results, there are two possibilities:

• Your model contains an error, in that it does not correctly express what you intended.
• Your expectations about how the model should behave were wrong.

You should first check the model carefully to make sure it contains no errors, and does indeed express what you intended. Explore the model to try to figure out how it generates the unexpected results. If after thorough exploration you can find no mistake, and the model persists in its unexpected behavior, do not despair! It may be that your intuitions were wrong in the first place. This discovery should be a cause for celebration rather than disappointment. If models always behaved exactly as expected, there would be little reason to build them. The most valuable insights come from models that behave counter-intuitively. When you understand how their behavior arises, you can deepen your understanding and improve your intuition — which is, after all, a fundamental goal of modeling.

Document as you build

Give your variables and modules meaningful titles, so that others — or you, when you revisit the model a year later — can more easily understand the model from looking at its influence diagrams. It’s better to call your variable $\text{Net rental income}$ than $\text{NRI23}$. 
It's also a good idea to document your model as you construct it by filling in the Description and Units attributes for each variable and module. You may find that entering a line or three of description for each variable, explaining clearly what the variable represents, will help to keep you clear about the model. Entering units of measurement for each variable can help you avoid simple mistakes in model specification. Avoid the temptation to put documentation off until the end of the project, when you may run out of time, or may have forgotten key aspects.

Most models, once built, spend the majority of their lives being used and modified by people other than their original author. Clear and thorough documentation pays continuing dividends; a model is incomplete without it.

Expanding your model

Extend the model by stages

The best way to develop a model of appropriate size is to start with a very simple model, and then to extend it in stages in those ways that appear to be most important. With this approach, you'll have a usable model early on. Moreover, you can analyze the sensitivities of the simple model to find out where the key uncertainties and gaps are, and use this to set priorities for expanding the model. If instead you try to create a large model from the start, you run the risk of running out of time or computer resources before you have anything usable. And you may end up putting much work into creating an elaborate module for an aspect of the problem that turns out to be of little importance.

Identify ways to improve the model

There are many ways to expand a model:

- Add variables that you think will be important.
- Add objectives or criteria for evaluating outcomes.
- Expand the number of decision options specified for a decision variable, or the number of possible outcomes for a discrete chance variable.
- Expand a single decision into two or more sequential decisions, with the later decision being made after more information is revealed.
- For a dynamic model, expand the time horizon (say, from 10 years to 20 years) or reduce the time steps (say, from annual to quarterly time periods).
- Disaggregate a variable by adding a dimension (say, projecting sales and costs by each division of the company instead of only for the company as a whole).
- Start with a deterministic model, then add probabilistic inputs to make the model probabilistic.

Before plunging in to one of these approaches to expanding a model, it's best to list the alternatives explicitly and think carefully about which is most likely to improve the model the most for the least effort. Where possible, perform experiments or sensitivity analysis to figure out how much effect alternative kinds of expansion may have.

Changing the size or numbers of dimensions of tables is a difficult and time-consuming task in conventional modeling environments. Analytica makes it relatively easy, since you only need to change those definitions that directly depend on the dimension (for example, the edit tables), and Analytica will propagate the needed changes automatically throughout the model.
A major advantage of starting with a simple model is that you use it to guide extensions in the ways that will be most valuable in improving the model’s results. You can analyze the sensitivities of the simple model (for example, using Importance Analysis, as described in “Importance analysis”) to identify which sources of uncertainty contribute most to the uncertainty in the results. Typically, only a handful of variables contribute the lion’s share of the overall uncertainty. You can then concentrate your future modeling efforts on those variables and avoid wasting your energy on variables whose influence is negligible.

Early intuitions about what aspects of a model are important are frequently wrong, and the results of the sensitivity analysis may come as a surprise. Consequently, it’s much safer to base model development on sensitivity analysis of simple models than to rely on your intuitions about where to spend your efforts in model construction.

Once you have identified the most important variables in your simple model, there are several ways to reduce the uncertainty they contribute. You can refine the estimated probability distribution by consulting a better-informed expert, by analyzing more existing data, by collecting new data, or by developing a more elaborate model to calculate the variable based on other available information.

Simplifying a model has many benefits. It becomes easier to understand and explain, faster to run, and cheaper to maintain. These savings may afford you the opportunity to extend parts of the model that are more important.
Chapter 6

Creating Lucid Influence Diagrams

This chapter offers guidelines for creating influence diagrams that are clear and comprehensible by careful arrangement of nodes, well-designed module hierarchies, and judicious use of color. It also describes how to adjust and align nodes, and customize styles for nodes and diagrams. Options include which arrows to show, node sizes, colors, text size, and font family.
Hierarchical influence diagrams can provide a lucid display of the essential qualitative structure of a model, uncluttered by quantitative details.
Guidelines for creating lucid and elegant diagrams

Where aesthetics are involved, rules cannot be hard and fast. You may adapt and modify these guidelines to suit your particular applications and preferences.

Use clear, meaningful node titles

Aim to make each diagram stand by itself and be as comprehensible as possible. Each node title can contain up to 255 characters of any kind, including spaces. Use clear, concise language in titles, not private codes or names (as are often used for naming computer variables). Mixed-case text (first letter uppercase and remaining letters lowercase) is clearer than all letters uppercase.
Use consistent node sizes

Diagrams usually look best if most of the variable nodes are of the same size:

Node sizes will be uniform if you set the default minimum node size in the Diagram Style dialog (see “Diagram Style dialog”) large enough so that it fits the title for nodes. When creating nodes, it uses this default size unless the text is too lengthy, in which case it expands the node vertically to fit the text. For more information on how to adjust node sizes see “Adjust node size” on page 75.

To make nodes the same size, select the nodes (Control+a selects all in the diagram), and select Make same size > Both from the Diagram menu (or press = key twice).

Use small and large nodes sparingly

Sometimes, it is effective to make a few special nodes extra large or small. For example, start and end nodes, which may link to other models, often look best when they are very small. Or you may make a few nodes containing large input tables or modules containing the "guts" of a model larger to convey their importance.

Arrange nodes from left to right (or top to bottom)

People find it natural to read diagrams, like text, from left to right, or top to bottom. Try to put the decision node(s) on the left or top and the objective node(s) on the right or bottom of the diagram, with all of the other variables or modules arranged between them.

You may need to let a few arrows go counter to the general flow to reduce crossings or overlaps. In dynamic models, time-lagged feedback loops (shown as gray arrows) may appropriately go counter to the general flow.

1. Or right to left for models in Arabic or Hebrew.
Tolerate spaghetti at first... It is often hard to figure out a clear diagram arrangement in advance. It is usually easiest to start a new model using the largest Diagram window you can: Click the maximize box to have the diagram fill your screen. You may want to create key decisions and other input nodes near the left or top of the window, and objectives or output nodes near the right or bottom of the window. Aside from that, create nodes wherever you like, without worrying too much about clarity.

...reorganize later When you start linking nodes, the diagram may start to look tangled. This is the time to start reorganizing the diagram to create some clarity. Try to move linked nodes together into a module. Develop vertical or horizontal lines of linked nodes. Accentuate symmetries, if you see them. Gradually, order will emerge.

Arranging nodes to make clear diagrams

Adjust node size If you have nodes of different sizes, you can make them more consistent by selecting Adjust Size (Control+t) from the Diagram menu. All of the selected nodes are resized to the default minimum node size, or the minimum size needed to enclose each node’s title, whichever is larger.

You can also resize several nodes by the same amount simultaneously by following these steps:

1. Select the nodes to resize.
2. Resize one of the selected nodes by dragging one of its handles. All the other selected nodes are also resized.

Selected nodes can also be set to be the same width, height, or size. To set the size of selected nodes to be the same size use the Make Same Size submenu in the Diagram menu. The options are:

- **Make Same Size Width** — Sets all the selected nodes to the width of the widest node
- **Make Same Size Height** — Sets all the selected nodes to the height of the tallest node
• **Make Same Size Both** — Sets all the selected nodes to the width of the widest node and the height of the tallest node

**Align to the grid**

It usually looks best to align nodes with their centers on the same horizontal or vertical lines, so that many arrows are exactly horizontal or vertical. The square grid of 9x9 pixel blocks underlying each diagram makes this easy. When the grid is on (the default), each node that you create or move is centered on a grid intersection. This default makes it easier for you to position nodes so that arrows are exactly horizontal or vertical when nodes are aligned vertically or horizontally.

To re-center nodes, select **Align Selection to Grid** from the **Diagram** menu (Control+j).

To turn the grid off in edit mode, uncheck **Snap to Grid** from the **Diagram** menu. When the grid is off in edit mode, the grid is still visible, and you can move the nodes pixel by pixel.

If nodes are not centered on a grid point, re-center them by following these steps:

1. Select all nodes in the diagram with the **Select All** (Control+a) command from the **Edit** menu.
2. Select **Align Selection To Grid** from the **Diagram** menu.

**Align selected nodes**

To line up selected nodes with each other, use the **Align** submenu in the **Diagram** menu. You can align selected nodes with one another in the following ways:

• Align their left edges
• Align their centers left and right — this aligns their centers horizontally
• Align their right edges
• Align their left and right edges — this makes all the selected nodes the same width and aligns, so that their left and right edges match up. All nodes will be set to the width of the widest node.
Chapter 6  Creating Lucid Influence Diagrams

Arranging nodes to make clear diagrams

- Align their top edges
- Align their centers up and down — this aligns the nodes so that their centers are at the same vertical height
- Align their bottom edges

Distributing nodes
To distribute selected nodes evenly, use the Space Evenly submenu in the Diagram menu. You can distribute selected nodes so that their centers are evenly spaced vertically (Space Evenly Across) or horizontally (Space Evenly Down).

Choosing which node is in front
By default, text and picture nodes are behind arrows, and arrows are behind all other types of nodes (decision, chance, variable, etc.). If nodes overlap, the more recently created node will be on top of the older node. You can change this order by selecting a node(s) and using the Send to Back and Bring to Front options from the right-click menu.

Hide less important arrows
Sometimes so many nodes are interrelated that it is hard or impossible to arrange a diagram to avoid arrows crossing each other or crossing nodes. It may be helpful to hide some arrows that show less important linkages. For example, indexes and functions are often connected to many other variables; that’s why arrows to and from them are switched off by default.
You can hide all of the arrows linking indexes, functions, or modules, or the grayed feedback arrows in dynamic models, using the **Set Diagram Style** command from the **Diagram** menu (see “Diagram Style dialog”). You can also hide the input or output arrows from each node individually, using the **Set Node Style** command (see “Node Style dialog”).

**Keep diagrams compact**

Screen space is valuable. To save space, keep nodes close together, leaving enough space between them for the arrows to be visible.

When first creating a diagram, use plenty of space. Your diagram window can be as large as your monitor screen. Using this space, first find a clear arrangement, which minimizes arrow crossing and avoids node overlaps. Then, you can usually make the diagram more compact by moving the nodes closer together and moving the entire diagram closer to the upper left corner of the window. Finally, you can reduce the window size to fit the diagram.

---

**A spread-out diagram**

---

**A compact diagram**
Organizing a module hierarchy

In addition to properly arranging the nodes in a single diagram, you can also improve the clarity of your models by using module hierarchies effectively.

Group related nodes in the same diagram

When assigning nodes to diagrams, the goal is to put groups of nodes that have many links among them in the same diagram, and to separate them from other groups with which they have few or no links. For example, the diagram below shows that a group of nodes related to annual housing costs have been organized into the Annual costs module within the larger model.

Sometimes you have a good idea of how to group nodes before you create them. In such cases, it is easy to create the modules first, and then create and link the nodes in groups in each module.

In other cases, it may not be obvious what groupings will work best. It is then often best to create all the nodes in a single large diagram. After drawing all the arrows, you may have a confusing spaghetti diagram. At this point, try to move the nodes around to identify groups containing 5 to 15 nodes, with many links within each group and fewer links between groups. When you arrive at a satisfactory grouping, create a module node for each group and move the group of variables into its own module.
Use 10 to 20 nodes per diagram

When creating a hierarchy of diagrams for a model with 100 variables, you could create a single module with 100 nodes, 10 modules with an average of 11 nodes each, 20 modules with 6 nodes each, or 50 modules with 3 nodes each.²

A module containing more than 20 nodes often looks overwhelmingly complicated, unless there are strong regularities in the structure. On the other hand, if modules have fewer than 5 nodes, you need so many modules that it is easy for users to get lost.

The range of 10 to 20 nodes per diagram is a good general goal. But don’t feel too constrained by it if a few diagrams are outside this range.

Contrast the module hierarchy in the illustration on page 79 with the spaghetti on page 73. The relationships among objects are much easier to see and understand in the model with 10 nodes in the top-level module and 12 nodes in the embedded module (page 79) than in the model with 24 top-level nodes (page 73).

Color in influence diagrams

Color can greatly improve the clarity and appeal of diagrams. The diagram’s background and its nodes have light colors by default. You can change the colors to meet your special needs.

Use colors judiciously

Garish or uncoordinated colors can be distracting. It generally looks messy to have nodes in many different colors. Sometimes it’s useful to use color coding beyond the default colors by class of node. For example, you might want to color all input nodes to identify them clearly.

Light colors work best because it’s easier to see the black arrows and text over light backgrounds. Analytica’s default colors provide a light neutral color for the background and a slightly stronger color for the nodes.

Recoloring nodes or background

1. In edit mode, select Show Color Palette from the Diagram menu:

2. Select the node or nodes you want to recolor, or to recolor the background, just click the background. The current color of the node(s) or background appears in the single square at the top of the color palette.

3. Click a color square to apply the new color to the nodes or background.

For a wider range of colors, click Other to display a full color chart.

Grouping nodes with a text box

It often improves the look and clarity of a user interface to group related nodes in rectangular boxes with a contrasting color, white in this case:

². Each module also creates a new node, so the total number of nodes is the number of variables plus the number of modules.
To create a grouping rectangle using a text box:

1. With the diagram in edit mode, create a **text node** by dragging from □ on the node toolbar onto the diagram.
2. Type a title into the text node, or leave it blank as desired.
3. Move and resize the node to enclose the group of inputs or outputs. You may find it convenient to deselect the **Resize centered** option from the **Diagram** menu.
4. With the node selected, open the **Set Node Style** dialog from the **Diagram** menu, check the **Border** and **Fill color** options (and **Bevel**, if you like), and click **OK**.
5. Select the **Color palette** from the **Diagram** menu, and click the preferred color for the node, e.g., white.

Usually, text nodes appear behind all other nodes, which is what you want for organizing groups. But if a node is not in the back and is obscuring other items, you can select **Send to Back** from the right-click button menu.

**Tip**

The background color of a diagram also applies to the background color of any modules contained in the diagram — unless you explicitly override the default by setting a different background color for each submodule. Similarly, the color you apply to a module node will also apply to any submodule nodes inside the module — unless you override the default by recoloring any submodule node(s).

### Diagram Style dialog

Use the **Diagram Style** dialog to customize the font size and typeface for nodes, whether arrows are displayed for specified node classes, and the node size. To display the **Diagram Style** dialog, select **Set Diagram Style** from the **Diagram** menu.
Creating Lucid Influence Diagrams

Show arrows to/from
- Check the corresponding boxes to display (or hide) arrows that go to and from nodes of each type, **Indexes**, **Functions**, **Modules**, and **Dynamic**. **Dynamic** controls the display of time-lagged dependencies to variables defined with **Dynamic**, usually displayed as gray arrows. See "Dynamic(initial1, initial2..., initialn, expr)" on page 298.

- By default, diagrams show arrows to and from modules and dynamic, but not indexes and functions. Showing more arrows can render some diagrams confusing with criss-crossing arrows. But, showing fewer arrows makes important dependencies (influences) invisible. The best balance depends on the model.

Default node size
- Drag the handle in this box to set the default node size. When you create a new variable or select the **Adjust Size** command from the **Diagram** menu, it tries to make the node this size — if the node title is too large, it expands the node vertically until it fits. It is usually best to size the default to include at least two lines of text at the selected font size.

- Input and output nodes do **not** use this default; they extend horizontally to fit their text plus field or button.

Font Style
- To change the default font size, use the menu or type in a font size (in typographic points). Select the default typeface from the font menu.

Overriding diagram defaults
- The **Diagram Style** dialog sets defaults for the diagram and for any modules contained in that diagram. You may override these defaults for particular nodes with the **Node Style** dialog (below), or for a submodule by using the **Diagram style** dialog for the submodule.

---

**Node Style dialog**

The **Node Style** dialog lets you customize the display of one or more nodes in a diagram. You can change the typeface and font size, and whether to display the incoming and outgoing arrows, the text label, border, fill color, and bevel, and the text size and font. These options override any defaults set for in the **Diagram Style** dialog.

**To open the Node Style dialog**
1. Select one or more nodes in a diagram.
2. Choose **Set Node Style** from the **Diagram** menu or the **right-click** menu.
3. Select the options for which you want to override the default styles.
4. Click OK.

**Input arrows** Check to display arrows into this node.

**Output arrows** Check to display arrows out of this node.

By default, input and output arrows are not displayed for index and function nodes.

**Label** Check to display the title in the node. By default, this is checked for all nodes.

**Border** Check to display a thin black border around the node.

**Fill color** Check to display the color in the node. Otherwise the node appears transparent, and any nodes or arrows under it will be visible.

**Bevel** Check to show a bevel effect around the node. By default, this is checked only for button nodes.

By default, text nodes, input and output nodes do not show arrows, border or fill color.

**Tip** A grayed out check box indicates that this option is not the same for all selected nodes. If you leave it unchanged (gray), each node keeps its current setting. If you change it (on or off), it changes all nodes to the new setting.

**Font style** To override the default diagram font, select Use custom font. Then you can select the font size and typestyle.

## Taking screenshots of diagrams

These are some tips for taking good screenshots of influence diagrams and other Analytica windows for use in other documents or printing.

**Use browse mode** When making screen captures of a Diagram window, select browse mode \( \text{Browse mode} \) rather than the edit or arrow mode to switch off the background grid, which makes the diagram clearer.
### Switch off cross-hatching

By default, the nodes of undefined variables show a cross-hatched pattern around the title. To remove this pattern, uncheck **Show undefined** in the **Preferences** dialog from the **Edit** menu (see “Preferences dialog”).

### Diagram colors

Use white for the background if you plan to print screenshots of the diagram on a black and white printer at less than 600 dpi (dots per inch). The print command lets you not print the background color if any.
This chapter shows you how to control the display of numbers, including Booleans and dates, in tables and styles and options for graphs.
Number formats

The Number format dialog box lets you control the format of numbers to display in result tables and graphs — including dates and Booleans. You can select options like the number of decimal digits, currency signs, and commas to separate thousands. The default number format is suffix, which uses a letter following the number, such 10K to mean 10,000 (where K means Kilo or thousands).

The number format of a variable is used wherever the value of that variable appears — in a result table, graph, input or output field. The number format of an Index applies wherever that index is used, including row or column headers of a table, or along an axis of a graph that uses that index.

You may enter a number into an expression or table in any format, no matter what output format it uses — except for dates, where you need to specify a date format, so that it will interpret 10/10/2007, for example, as a date, not two divisions.

To set the number format for a variable:

1. Select a variable by showing its edit table, result table, or graph, or by selecting its node in a diagram. To apply the same format to multiple variables, select their nodes together in a diagram.

2. Select Number format from the Result menu, or press Control+b, to show this dialog:

3. Select the format you want from the list on the left.

4. Select options you want, such as Decimal digits, Show trailing zeroes, or Thousands separators, or Show currency symbol.

5. Check the example at the top of the dialog to see if it’s what you want.

6. If so, click the Apply button.
Format types

Choose one of these number formats:

<table>
<thead>
<tr>
<th>Format</th>
<th>Description</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>Suffix</td>
<td>A letter after the number specifies powers of ten (see below for details)</td>
<td>12.35K</td>
</tr>
<tr>
<td>Exponential</td>
<td>Scientific or exponential notation. The number after the “e” gives the powers of ten.</td>
<td>1.235e04</td>
</tr>
<tr>
<td>Fixed Point</td>
<td>A decimal point with fixed number of decimal digits</td>
<td>12345.68</td>
</tr>
<tr>
<td>Integer</td>
<td>A whole number with no decimals</td>
<td>12346</td>
</tr>
<tr>
<td>Percent</td>
<td>A percentage</td>
<td>12%</td>
</tr>
<tr>
<td>Date</td>
<td>Date (see below for details)</td>
<td>12 Jan 2007</td>
</tr>
<tr>
<td>Boolean</td>
<td>Displays 0 as False, any other number as True.</td>
<td>True, False</td>
</tr>
</tbody>
</table>

Suffix characters

Suffix is Analytica’s default format. It uses a conventional letter after each number to specify powers of 10: 12K means 12,000 (K for kilo or thousands), 2.5M means 2,500,000 (M for Mega or millions), 5n means 0.000,000,005 (n means nano or billionths). Here are all the suffix characters:

<table>
<thead>
<tr>
<th>Power of 10</th>
<th>Suffix</th>
<th>Prefix</th>
<th>Power of 10</th>
<th>Suffix</th>
<th>Prefix</th>
</tr>
</thead>
<tbody>
<tr>
<td>10⁻²</td>
<td>%</td>
<td>percent</td>
<td>10⁻³</td>
<td>m</td>
<td>milli</td>
</tr>
<tr>
<td>10⁻⁶</td>
<td>µ</td>
<td>micro (mu)</td>
<td>10⁻⁹</td>
<td>n</td>
<td>nano</td>
</tr>
<tr>
<td>10⁻¹²</td>
<td>p</td>
<td>pico</td>
<td>10⁻¹⁵</td>
<td>f</td>
<td>femto</td>
</tr>
</tbody>
</table>

Tip

Note the difference between ‘M’ for Mega or Million and ‘m’ for milli (1/1000). This is the only situation in which Analytica cares about the difference between upper- and lowercase. Otherwise, it is insensitive to case (except when matching text values).

Tip

In suffix format, it displays four-digit numbers without the ‘K’ suffix, which looks better for years — e.g., 2010, not 2.010K. For suffix, integer, or fixed point formats, it uses exponent format for numbers too large or small — e.g., numbers larger than 10⁹ in integer or fixed point format, or larger than 10¹⁸ in suffix format.

Maximum precision

The maximum number of digits including decimal digits is 15 (14 for fixed point and percent); the maximum number precision is 15 digits (9 for integers).

Number format options

Decimal digits

The number of digits to show after the decimal point.
Chapter 7 Formatting Numbers, Tables, and Graphs

**Show trailing zeroes**
Check to show trailing zeroes in decimals, e.g., 2.100 instead of 2.1, when decimal digits are set to 3.

**Thousands separators**
Check to show commas between every third digit of the integer part, e.g., 12,345.678, instead of 12345.678.

**Show currency symbol**
Check to show a currency symbol. Select the symbol and placement from these menus:

![Currency Symbol Menu](image)

Placement controls the relative location of the currency symbol, e.g., $200 or 200DM, and whether to use a minus sign -$200 or parentheses ($200) to indicate a negative number.

**Regional settings**
If you select the last entry, “regional”, from the Symbol or Placement menu, it uses, respectively, the regional currency or placement settings set for your computer. You can modify these settings in the Regional and Language options available from the Windows Control Panel.

## Date formats

A date is a number shown in Date format. The date number represents the date as the number of days since the *date origin*, usually Jan 1, 1904.

![Date Format Window](image)
The **Date** format in the **Number format** dialog offers these options:

- **Short**: e.g., 8/5/2006
- **Abbrev**: e.g., Aug-5-2006
- **Long**: e.g., Thursday, 05 August, 2006
- **Custom**: Use an existing custom format or set up a new one, for example:

<table>
<thead>
<tr>
<th>Date format</th>
<th>Displays as</th>
</tr>
</thead>
<tbody>
<tr>
<td>dd-MM-yy</td>
<td>05-8-06</td>
</tr>
<tr>
<td>‘Q’Q YYYY</td>
<td>Q2 2006</td>
</tr>
<tr>
<td>www, d MMM yyyy</td>
<td>Thu, 5 Aug 2006</td>
</tr>
<tr>
<td>wwww, d of MMMM, yyyy</td>
<td>Thursday, 5 of August, 2006</td>
</tr>
</tbody>
</table>

**Date format codes** Custom date format uses these letter codes, conventional for Microsoft Windows:

<table>
<thead>
<tr>
<th>Code</th>
<th>Description</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>d</td>
<td>numeric day of the month as one digit</td>
<td>1, 2, … 31</td>
</tr>
<tr>
<td>dd</td>
<td>numeric day of the month as two digits</td>
<td>01, 02, … 31</td>
</tr>
<tr>
<td>ddd</td>
<td>ordinal day of month in numeric format</td>
<td>1st, 2nd, … 31st</td>
</tr>
<tr>
<td>dddd</td>
<td>ordinal day of month in text format</td>
<td>first, second, … thirty-first</td>
</tr>
<tr>
<td>Dddd</td>
<td>capitalized ordinal of month</td>
<td>First, Second, … Thirty-first</td>
</tr>
<tr>
<td>wwww</td>
<td>weekday in three letters</td>
<td>Mon, Tue, … Sun</td>
</tr>
<tr>
<td>wwwww</td>
<td>weekday in full</td>
<td>Monday, Tuesday, … Sunday</td>
</tr>
<tr>
<td>M</td>
<td>month as a number</td>
<td>1, 2, … 12</td>
</tr>
<tr>
<td>MM</td>
<td>month as two-digit number</td>
<td>01, 02, … 12</td>
</tr>
<tr>
<td>MMM</td>
<td>month as three letter name</td>
<td>Jan, Feb, … Dec</td>
</tr>
<tr>
<td>MMMM</td>
<td>month as full name</td>
<td>January, February, … December</td>
</tr>
<tr>
<td>q</td>
<td>quarter as one digit</td>
<td>1, 2, 3, 4</td>
</tr>
<tr>
<td>yy</td>
<td>year as two digits</td>
<td>e.g., 99, 00, 01</td>
</tr>
<tr>
<td>yyyy</td>
<td>year as four digits</td>
<td>e.g., 1999, 2000, 2001</td>
</tr>
</tbody>
</table>

**Tip**
To show literal text within the date, enclose it in quotes, e.g., ‘q’t → q2.

**Interpreting input dates**
If you specify any date format for an input variable or edit table, you can enter dates in any acceptable date format. For example, a variable with a date format, interprets 1/5/2005 as **5 January, 2005** on a computer set to **USA region** or 1 **May, 2005** elsewhere. Without the date format, it would interpret 1/5/2005 as (1 divided by 5) divided by 2005!

**Regional and language settings**
The language for day and month names and the formats used for **Short** and **Long** dates depend on the regional settings for Windows. In the U.S., you might see a short date as 9/11/2001, but in Denmark you might see 11.9.2001. You can review and change these settings in **Regional and Language options** available from the Windows Control Panel. These apply to Analytica and all standard Windows applications. To modify settings, click the **Customize** button and select either the **Date** tab or **Languages** tab. For example, if you set the language to **Spanish (Argentina)**, a variable with the **Long** date setting, the date displays as:

**StartDate** → **Sábado, 03 de Febrero de 2007**
where

\[
\text{Variable StartDate := Makedate(2007, 2, 3)}
\]

**Date numbers and the date origin**

Analytica represents a date as a *date number*, that is, the number of days since the *date origin*. By default, the date origin is Jan 1, 1904, as used by most Macintosh applications, including Excel on Macintosh, and all releases of Analytica on Macintosh and Windows up to Analytica 3.1. If you check **Use Excel date origin** in the Preferences dialog, the date origin is Jan 1, 1900, as used by default in Excel on Windows and most other Windows software.

With **Use Excel date origin** checked, the numeric value of dates are the same in Analytica and Excel for Windows for dates falling on or after 1 Mar 1900. Because of a bug in Excel, in which Excel incorrectly treats Feb 29, 1900 as a valid day (1900 was not really a leap year), dates falling before that date do not have the same numeric index in Analytica as they do in Excel.

When using models containing dates or date functions from Analytica releases 3.1 or earlier, you should keep **Use Excel date origin** unchecked. If you want to paste or link values from Excel or other Windows software to or from Analytica, you should check this option.

**Range of dates**

Analytica can handle dates from 1 CE to well beyond 9999 CE (CE means Common Era or Christian Era, and is the same as AD.). Dates earlier than the date origin are represented as negative integers. Dates use the Gregorian calendar, so years divisible by 4 are leap years and those divisible by 100 are not leap years, except those divisible by 400 which are leap years.

**Date arithmetic and functions**

You can simply add an integer \( n \) to a date to get the date \( n \) days ahead. See “Date functions” for *MakeDate()*, *DatePart()*, *DateAdd()*, and *Today()*.

### Multiple formats in one table

Usually, the same number format applies to all numbers in a table (except its index values in column or row headers, which use the format set for the index variable.) Sometimes, you may want to use different formats for different rows (more generally, slices) of a table. You can do this if you define the table as a list of variables, for example:

\[
\text{Index Years := 2007..2012} \\
\text{Variable DollarX := Table(Years)(...) \{ Formatted as dollars \}} \\
\text{Variable PercentX := DollarX/40JK \{ Formatted as percent \}} \\
\text{Variable MultiformatX := [DollarX, PercentX]}}
\]

![Result - MultiformatX](image)
Graphing roles

A **graphing role** is an aspect of a graph or chart used to display a dimension (or index) of an array value; they include the horizontal axis, vertical axis, and key. A simple key uses colors, but you can expand it to include a symbol shape and size for each data point. When the array has too many dimensions to assign them all graphing roles, you can assign the extra indexes as slicer dimensions, from which you can select any value to display. For each available role, a graph shows a menu from which you can select the index you want to assign to that role. The flexibility of being able to directly assign graphing dimensions (such as indexes) to roles on the graph helps you find the best way to communicate multidimensional results. Graphing roles can display a continuous numeric scale or a discrete numerical or categorical scale — except for symbol size which must be numerical.

This example shows projections of US energy consumption made by two organizations, the US Energy Information Administration (actual) and the Alliance for Renewable Energy (fictional). The horizontal axis is set to **Energy source**, the key (color) is set to **Organization**, leaving the **Year** as a slicer, from which we have selected 2025:
Here we have changed graphing roles, assigning **Year** to the horizontal axis, **Energy source** to the color key, and **Organization** to the symbol key, leaving no need for a slicer:

In this version, the color key and symbol key both show the **Organization** index. The index **Energy source** is not assigned a visible graphing role, so shows up as a slicer. It is set to **Totals**, to show total over energy sources for each organization:
These are the graphing roles available:

**Vertical axis**  Simply the vertical direction, labeled along the left edge of the graph. By default, it shows the actual values in the array — other roles usually show values of an index. All graphs use this role, but the Vertical Axis menu only appears if you have set Swap horizontal and vertical in the Graph setup dialog (page 94) or for XY graphs (page 105).

**Horizontal axis**  The horizontal direction, labelled with numbers or text along the lower edge of the graph. It always appears, except when you set Swap horizontal and vertical for a 1D array. In the table view, it becomes the column headers.

**Key**  Defines the color of lines or symbols. By default, it appears for the second index, if the array has more than one dimension. The key appears below the graph — unless reset in the Style tab of Graph setup (page 94). In the table view, it becomes the row headers.

**Color key and symbol key**  If you check Use separate color/symbol keys in Graph setup (page 94) (available for the two line styles that show symbols), it expands the key into two graphing roles, color key and symbol key. Each has its own role menu, letting you assign a second and third index.

**Symbol size key**  If you further check Allow variable symbol size, it adds symbol size as a fourth graphic role. You can specify the range of sizes from smallest to largest in typographic points, corresponding to smallest and largest values of the corresponding index. (It only works for a numerical index.) Symbol key and symbol size key do not appear in the Table view.

**Slicers**  If the array has a dimension not assigned to a visible graphing role, it appears as a slicer — a menu above the graph. The value you select from a slicer menu applies to the entire graph, so the graph does not show values for other elements of the slicer. You can also select “Totals” from a slicer to show the total over all numerical values over that index. Slicers appear the same in the table as in the Graph view. If you have more than
one slicer, you can reorder them from top to bottom, in edit mode, simply by dragging a slicer up or down.

## Graph setup dialog box

The **Graph setup** dialog box lets you apply a wide variety of graphing styles and options to the selected graph, or as the new defaults for all graphs in this model. It also lets you use or define graph templates, to apply a standard collection of styles and options to a graph.

When you display the result of a variable, it shows it as a table or graph, according to how you last viewed it. The first time you view a result, it appears as a graph, unless you changed the default result view in the **Preferences** dialog.

When displaying a graph, Analytica uses the default graphing settings, unless you have selected other settings for it. You can modify these with the **Graph setup** dialog.

### To open the Graph setup dialog

First display a graph. Then do one of these:

- Select **Graph Setup** from the **Result** menu.
- Select **Graph Setup** from the right mouse button menu.
- Double-click the graph in the **Result** window.

The graph setup dialog has six tabs. All tabs show the template panel and these three buttons:

- **Apply**: Apply any changes to settings to the current graph, and close the dialog.
- **Set Default**: Save any changed settings on the current tab as the default for all graphs, and close the dialog. It does not affect any settings that you have not changed since you opened the **Graph setup** dialog. Changing a default affects all graphs that use the default, but not graphs for which you override the default (in the past or future).
- **Cancel**: Close the dialog without changing or saving anything.

### Chart Type tab

This tab shows options for modifying the style and arrangement of the graph:
Chapter 7  Formatting Numbers, Tables, and Graphs

Graph setup dialog box

**Graph setup**

- **Line style settings:**
  - Swap horizontal and vertical
  - 3-D effects

**Line style settings**

- **Area fill:** Check to fill in the area beneath each line with a solid color. If there are multiple lines, the graph will have a *key index*. It draws the fill areas from last to first element of the key index, which works well if the y values are sorted from smallest to largest over the key index. Otherwise, later values will obscure earlier ones. Here’s an example:

<table>
<thead>
<tr>
<th>Line style</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Line segments join the data points.</td>
<td></td>
</tr>
<tr>
<td>Line segments, with a symbol at each data point.</td>
<td></td>
</tr>
<tr>
<td>A symbol at each data point with no lines.</td>
<td></td>
</tr>
<tr>
<td>A pixel at each data point, with no line.</td>
<td></td>
</tr>
<tr>
<td>A histogram or step function, with a vertical line and horizontal line from each data point to the next.</td>
<td></td>
</tr>
<tr>
<td>A bar centered on each x value, with height showing the y value. Forces the graph to be discrete.</td>
<td></td>
</tr>
</tbody>
</table>

Swap horizontal and vertical

Check this box to exchange the x and y axes, so that x axis is vertical and y axis is horizontal. If x values are discrete with long labels, swapping axes gives a more easily legible bar graph.

3-D effects

Check to use three-dimensional style to view graphs. For a bar graph line style, it offers the choice of **Box** or **Cylindrical** shapes for the bars.

Line style settings

Displays when you select a line style showing lines.

- **Area fill:** Check to fill in the area beneath each line with a solid color. If there are multiple lines, the graph will have a *key index*. It draws the fill areas from last to first element of the key index, which works well if the y values are sorted from smallest to largest over the key index. Otherwise, later values will obscure earlier ones. Here’s an example:
• **Transparency**: Drag the cursor to change transparency of fill colors between opaque and transparent. Transparency lets you see fill lines and areas that would otherwise be obscured behind others.

• **Line thickness**: Select the thickness of lines to display. (Only for styles that show lines.)

• **Use separate color/symbol keys**: Check to display two key index roles, one indicated by color and the other by symbol type or size.

• **Allow variable symbol size**: Check to have the size of symbols vary with their value.

• **Symbol size**: Enter a number to specify size of symbols in typographic points.

• **Min symbol size and Max symbol size**: If you check **Allow variable symbol size**, use these fields to specify the range of symbol sizes from smallest and largest.

**Bar graph settings** Displays when you select **Bar** graph line style:

• **Stacked bars**: Check to show bars stacked one on top of the other over the key index, instead of side by side. The values for each bar are cumulated over the key index.

• **Variable origin**: Check if you want to set the origin (starting point) for each bar other than zero (the default). The graph will then display a **Bar Origin** menu to let you select the bar origin.

• **Bar overlap**: With stacked bars, they overlap 100%. You can specify partial overlap between 0 and 100%.
**Axis Ranges tab**

This tab lets you control the display for each axis, vertical and horizontal, including scaling, range, and tickmarks:

**Graph setup dialog box**

**Autoscale**  Uncheck this box if you want to specify the range for the axis, instead of letting Analytica select the range automatically to include all values.

**Max and Min**  The maximum and minimum values of the range to use when you have unchecked **Autoscale**.

**Include zero**  Check if you want to include the origin (zero) in the range.

**Approx. # ticks**  Specify the number of tick marks to display along the axis. Analytica might not match the number exactly, in the interests of clarity.

**Reverse order**  Check this box if you want to show the values ordered from large to small instead of the default small to large.

**Categorical**  Treat this axis as categorical. Usually, Analytica figures out the quantity is categorical without help. Occasionally, if the values are numerical, you might want to control it yourself. See “Probability density and mass graphs”.

**Log scale**  Check if you want to display this on a log scale. This is useful for numbers that vary by several orders of magnitude. It uses a “double log” scale with zero if the values include negative and positive numbers.

**Set default**  If you have changed settings for an axis that is an index of the variable being graphed, clicking this button applies these changes to that index for **all** graphs that use that index. For example, if the scale is the **Index Time**, you can use this to change the **Time** scale (e.g., start and end year) for every graph that displays a value over **Time**, unless you want to override that default in another graph.

**Style tab**

The **Style** tab lets you modify the display of the style and color of the grid, frame, and tick marks, and where to display the key.
Grid  Select the radio button to control the display of the grid over the graphing area. You can also select the color. A light or medium gray is often a good choice.

Frame  Select the radio button to control the display of the lines framing the graphing area. You can also select the color for the frame. It is usually best to make the frame the same color as the grid, or a darker shade of the same color.

Tick marks:  The top radio buttons control where to show tick marks. The lower ones control how they are displayed.

Display key  Select the radio button to control where to display the key on the graph. Select the Show border check box to display an outline rectangle around the key.

Text tab

The Text tab lets you change the font, size, style, and color on the graph for the text of axis titles, axis labels (i.e., numbers or text identifying points along each axis), key titles, and key labels (i.e., identifying values in the key).
Font  Select the font family. Graphic designers recommend using the same font for all text, which you can easily do by leaving all except axis titles as "(Same as axis titles)".

Size  The size in typographic points. Set to 0 if you want that type of text to not display.

Color  Select the color.

Bold, Italics, and Underline  Check these boxes to add bold, italic, and underlined formats to the text.

Axis label rotation  Enter a number from -90 to 90 degrees to rotate the labels for each axis. For example, for a bar graph with many long labels along the horizontal axis, they won't all fit. By rotating them by 45 or 90 degrees, you can make them all fit without getting truncated.

Adapt displayed font sizes to graph height  If you check this box, the font size automatically adjusts when you make the graph window larger or smaller. This can be useful when you give a demo and want to expand graphs so they are easily readable to people at the back of the room. The font sizes match those specified at the default graph height of 300 pixels.

Background tab

This tab lets you control the fill color, gradient, or pattern on the graph background. The main area covers the entire graph window (exclusive of the top area containing indexes). The plot area is the rectangle showing the graph values. If you leave or set the Fill to None for the Plot area or Key area, they will show the same fill settings (if any) as the Main area.
Fill  Select from:

- **None**: No fill. Default to blank (white) background.
- **Solid**: Use a solid fill with the selected **Color 1**.
- **Gradient**: Use a gradient of color, going from **Color 1** to **Color 2**, in the direction you specify in **Gradient style**.
- **Hatch**: Use a hatched fill using the selected **Hatch Style** with **Color 1** and **Color 2**. Graphic designers recommend avoiding hatched backgrounds, and using solid or gradient backgrounds with pale colors, if at all. The data should not be overwhelmed by the background.

Preview tab

This tab shows the graph using the current settings so that you can see their effects before you decide to **Apply** or **Cancel** them.
Categorical and Continuous Plots

Analytica 4.0 gives much more attention and consistency to the treatment of categorical, continuous, and discrete results.

The discrete vs. continuous distinction is determined by the domain attribute, and determines whether probability plots are density and cumulative density plots (continuous) or probability mass and cumulative probability (discrete) plots.

The categorical vs. continuous distinction determines how a graphing axis is laid out. Continuous dimensions require numeric values. The determination of whether a graphing dimension is categorical or continuous is partially determined by the domain attribute. However, the values actually occurring in the dimension are determined by the chart type (bar or non-bar chart) and by the Categorical checkbox in the axis range setting.

Exporting graph image type

You can export a graph as an image file in most common formats, including BMP, JPEG, TFF, PNG, and Enhanced Windows Metafile (EMF):

1. Display the graph the way you want.
2. Select Export from the File menu, to open the Save Graph Image as file browser dialog.
Graph templates

Graph templates let you apply a collection of graph settings to several graphs, or even to all the graphs in a model. Analytica 4.0 includes several standard templates. You can also define your own templates to create standard graphing styles for a model, project, or an entire organization.

To use a graph style template

To apply an existing graph template to a graph:

1. Double click your graph to open the Graph setup dialog.
2. From the Style template menu at the bottom of the dialog, select the template you want.
3. To see what the templates look like, click the Preview tab. As you select each template from the Style template menu, it applies it to the selected graph. All template settings will be reflected in the settings in the other tabs.
4. If you want to modify any other settings beyond what the template specifies, you can do so now.
5. When you are happy with the results (check them in the Preview tab), click Apply, or if you don't like any of them, click Cancel.

To stop using a graph style template

If you have a graph that uses a template T, and you wish to unlink it from the template, change the Style Template menu back from T to Global Default. It asks “Do you want to retain these styles for this graph?” If you answer yes, it copies the template settings to be local for this variable, so it looks the same, but future changes to the template have no effect. If you answer no, it removes the template settings from this graph so it reverts to the global defaults.
To define a new graph style template

To create a new graph template so you can reuse a collection of graph settings for other variables:

1. Open the **Graph setup** dialog by double-clicking the graph with the settings you want to reuse, or if you want to save only new settings, open it for a new variable.
2. If you want to modify or add any settings, make those changes. You can also make a new template with changes to an existing template: In that case, select the existing template and click **Apply template**.
3. Click the **Preview** tab to see what all settings will look like.
4. From the **Style Template** menu, select **New Template**.
5. Type in a name for the template.
6. Click the **Set Template** button.

You have now created a new template, which will be saved with the model. You can apply it to any graph in the model.

To modify a graph style template

To modify an existing graph style template $T$:

1. Open the **Graph setup** dialog by double-clicking a graph for variable $v$.
2. If variable $v$ does not already use template $T$, select $T$ from the **Style template** menu.
3. Modify any **Graph settings** you want for $T$.
4. Check the effect in the **Preview** tab.
5. When satisfied, click **Set template**.

Any changes you make to a template will affect all variables that use it, except for any local settings that override them for a particular variable.

Combining local, template, and model default settings

You can apply graph settings, and most uncertainty settings, at three levels:

- **Local**: Clicking **Apply** in the **Graph setup** or **Uncertainty Setup** dialog applies any settings you have modified in the dialog to the current variable. These settings override any global or template settings.

- **Graph template**: By selecting a style template in the **Graph setup** dialog and clicking **Apply**, you apply the template settings to the current variable. The template overrides any global settings, but not local settings.

- **Model defaults**: Clicking **Set Default** in the **Graph setup** or **Uncertainty Setup** dialog changes the global defaults for the model for any settings you have modified in the dialog.
Tip
If you change a global setting by clicking Set default, that change will change that setting for all graphs that do not override it by a template or a local setting.

The Uncertainty sample tab of the Uncertainty Setup dialog is an exception: Settings on that tab — e.g., Sample size — are always defaults that affect the entire model. They cannot be local and are not saved in a graph template.

Saving defaults as a template model

Analytica comes with a wide variety of standard defaults for graph settings, uncertainty options, preferences, diagram style, and more. If you want to save nonstandard default settings for these, perhaps also including graph templates and libraries so that you can use them for new models, the easiest method is to create a new template model:

1. Find or build a model that has all the default settings you want, including any graph settings, uncertainty settings, preferences, diagram style, graph templates, and user-defined attributes. It could also contain any libraries that you will want in all the new models.

2. Select Save as from the File menu to save the model under a new name, e.g., Template.ANA.

3. Delete all the contents of the model that you won’t need for new models.

4. Select Exit from the File menu and save the model.

Whenever you want to start a new model using these defaults, double-click Template.ANA, and save the model under a new name. To protect your template model from you accidentally changing it by saving a new model over it with the same name:

1. In the Windows Finder, open the folder containing Template.ANA.

2. Right-click Template.ANA, and select Properties.

3. Check the Read-only attribute, and click OK.

Graph templates and setting associations

Chart type and uncertainty views
Graph settings from the Chart type tab are associated with particular uncertainty views. For example, if you set Line style to symbols only (instead of the default pixel per data point) for a Sample plot, that line style will apply to any sample plot, but not to other uncertainty views Mid, Mean, Statistics, PDF, or CDF. Thus, you may set a different Style setting for each uncertainty view, except Mid, Mean, and Probability Bands, which share the same style.

Settings for discrete vs. continuous
It maintains separate line-style settings for continuous and discrete (categorical) plots. So, pivoting a continuous dimension to the x-axis to replace what was a discrete dimension may change the plot from a bar graph to line graph, and use the corresponding settings.

Axes and indexes
If the horizontal axis is an index (as it usually is), any settings on the Axes Ranges tab apply to that index only. For example, suppose variable Earthquake_damage is indexed on the horizontal axis by Richter_scale. You set Richter_scale to Log scale, and save into a template T. If you use template T for another variable Y also indexed by Richter_scale, it also displays Richter_scale on a log scale. But, if Y is not indexed by Richter_scale, the Axis setting will have no effect.
Chapter 7  Formatting Numbers, Tables, and Graphs

Uncertainty options and graph templates

A graph template also saves non-default settings made in the Uncertainty setup dialog tabs: Statistics, Probability bands, Probability density, or Cumulative probability. These settings apply to the corresponding uncertainty view of any variable using the template. Changes to the Uncertainty sample tab, however — e.g., to Sample size — set global defaults, which affect the entire model. They are not associated with particular variable, or saved in a graph template.

Changing the global default

Global default specifies the default settings used by every graph unless overridden in the Graph setup dialog for that graph or by a template that it uses. If the Style Template menu says Global default, it means that the graph uses the global defaults with no template.

To modify the global defaults:

1. Select a new variable with no graph settings, or a graph whose settings you want to make the global default.
2. Double click the graph to open Graph setup dialog.
3. If you want, make further changes to the settings, and review them in the Preview tab.
4. From the Style template menu, select Global Default, if it isn't already selected.
5. Click Set default button.

Note: Changes to global defaults change all existing and new graphs that use those global defaults; that is, all that are not overridden by any graph settings specifically set for that graph or by a template that it uses.

To rename a graph style template

1. Open the Graph setup dialog, by double-clicking a graph.
2. In the Style template menu, select the graph template you want to rename.
3. Click the Style template menu to select the old name.
4. Type in the new name.
5. Click Set template.

Note: The template *name* is actually its Title attribute, not its identifier. So, renaming a template does not affect any variables that use it.

XY comparison

When you display a standard (non XY) graph of a variable, V, it plots the values of V up the vertical (Y) axis against an index of V along the horizontal (X) axis. If V has more than one dimension, you can choose which index to plot horizontally from the Horizontal Axis menu. With XY Comparison, in contrast, you can plot V against another variable, U, along the horizontal (X) axis, over a Common index of V and U. You can also
plot one slice of $V$ against another slice over a **Comparison Index**. (See “Scatter plots” to use XY comparison for scatter plots.)

### XY comparison sources dialog

This dialog lets you set options for XY comparison and extends or adds menus to the XY graph described below.

#### To open the dialog
Click the **XY** button in top right corner of **Result** window (graph or table). You must be in edit or arrow mode, so it is not available in Analytica editions or models confined to browse mode.

#### Use comparison index
Check this box if you want to compare one slice of the variable against another slice, slices selected from the Comparison index. The graph will show the **Comparison Index** menu from which you can select the index you want. The **Vertical Axis** and **Horizontal Axis** menus will then offer slices from the comparison index so that you can choose which two slices to plot against each other.

#### Use another variable
Check this box if you would like to compare the base variable by plotting it against one or more other variables (or simple expressions). When you check it, the following items appear:

- **Add**
  Click this button to open the **Object Finder** dialog to select a variable against which to plot the base variable. You can also use the **Object Finder** to select a function or operation from one of the relevant libraries. You can add up to five items.

- **Remove**
  Select a item from the list of other variables, and click this button to remove it from the list of variables for comparison.
Menus added to XY Comparison graph

An XY comparison graph adds a **Common index** and, sometimes, a **Comparison index** to the usual graphing roles menus on a graph or table.

**Comparison index**

This menu lists the indexes of the base variable. The **Horizontal Axis** and **Vertical Axis** menus each let you choose a slice from the selected comparison index to plot against each other. It appears on the graph when **Use comparison index** is checked in the **XY comparison sources** dialog.

**Common index**

It defines the correspondence among the variables or slices to be plotted against each other: Each value of the Common index identifies a data point on the graph, with vertical (X) and horizontal (Y) values from the variables or slices you have selected for those graphing roles. For a scatter plot, the common index should be **Iteration** (**Run**). It appears on the graph when one or both checkboxes on the **XY comparison sources** dialog are selected.

If **Use another variable** is checked in the **XY comparison sources** dialog, the common index will be an index in common to the base variable and other variable(s). If the variables have more than one index in common, **Common index** will be a menu from which you can choose the index you want.

If **Use comparison Index** is checked in the **XY comparison sources** dialog, Common index will show the index(es) of the base variable not selected for the Comparison index. Common index will be a menu if the variable has more than two indexes — leaving more than one for the Common index.

**Example: Plot one variable against another**

For example, suppose you have an index and two variables:

```plaintext
Index Degrees := Sequence(0, 360, 5)
Variable V := Sin(Degrees)
Variable U := Cos(Degrees)
```
For a standard graph of V against its index, Degrees, select V from the diagram and click the Result button (Control+r). Repeat with U to display the graph for U against Degrees:

For these graphs, we selected the symbol plus line line style from Graph setup to show the data points for each value of Degrees (page 95).

With XY Comparison, you can graph U against V, instead of against its index Degrees:

1. Change to edit mode. In the Graph window for U, click the XY button in the top right corner (above) to open the XY Comparison sources dialog box.
2. Select checkbox **Use another variable**.
3. Click **Add** button to open the **Object Finder** dialog.

4. Select the variable **V**, and click **OK**. You can now see **V** listed in the **XY comparison sources** dialog.
5. Click OK.

The graph of $U$ now plots the values of $U$ on the vertical (Y) axis against corresponding values of $V$ on the horizontal (X) axis. By "corresponding" we mean for each value of Degrees, in the Common index. If $U$ and $V$ had more than one index in common, it would show a menu from which you could select the index you want.

Example: Compare variables using comparison index

You can also use XY Comparison to compare one slice of a variable against another slice of the same variable. This is especially useful when you combine several variables as a list. Let's add a third variable to $U$ and $V$ defined above:

Variable $W := \sin(2\times\text{Degrees})$

The parameter $2\times\text{Degrees}$ creates a sine curve with twice the frequency. Here is an easy way to create a list to compare several variables:
1. Select the three nodes for the variables to compare, U, V, and W, and click Result (Control+r).

2. When it prompts,

   ![Image of the Result window showing a question]

   click OK.

It creates a new variable Compare1, and shows the standard (not XY) graph comparing U, V, and W against Index Degrees:

![Image of the result graph showing U, V, and W against Degrees]

3. Make sure you are in edit mode. In the graph window for Compare1, click the XY button in the top right corner to open the XY comparison sources dialog box.
4. Select checkbox **Use comparison index** and click **OK**.

This sideways figure of 8 results because $W$ is a sine wave with twice the frequency of $V$. You can select other pairs of variables to compare, from $U$, $V$, and $W$, from the **Vertical** and **Horizontal Axis** menus — for example, changing to $W$ against $V$ puts the figure of 8 the right way up:
You can also select Degrees from the Horizontal Axis menu to revert to a standard (non XY) graph of the selected variable against Degrees.
Chapter 8

Creating and Editing Definitions

This chapter shows you how to:

• Create definitions
• Edit definitions
• Use the Object Finder
• Check the validity of a variable’s value
This chapter introduces the tools for creating and editing mathematical models by giving each variable a formula that defines how to compute its value in its definition. The definition of a variable can be a simple number, text, a probability distribution, or a more complicated expression. It can also be a list or table of numbers or other expressions. Subsequent chapters present more details about using mathematical expressions, arrays, and probability distributions.

Creating or editing a definition

To create or edit the definition of a variable, first be sure that the edit tool is selected. Select the variable of interest and do any of the following:

- Click in the toolbar, or press Control+e.
- Select Edit Definition from the Definition menu.
- Double-click the variable to open its Object window. Then click in the definition field.
- Click the key icon to open the Attribute panel of the diagram. Select Definition from the Attribute popup menu. Then click in the definition field.

If you have drawn arrows into this variable from other variables (Down_payment and Buying_price in this example), they appear in the Inputs popup menu. Select an input to paste its identifier into the definition. (The menu doesn’t appear if the variable has no inputs.)
Tip

If you are editing in the attribute panel, a handy way to insert the identifier of a node into
the definition is to click the node while pressing the Alt key. It only works for nodes in the
same diagram.

To edit a definition that is a simple number, text, or other expression:

1. Select the definition.
2. Edit it by typing, by deleting, or by using the standard text editing operators — that
   is, Copy (Control+c), Cut (Control+x), and Paste (Control+v).

See Chapter 10, “Using Expressions”, for the syntax of numbers, operators, simple
expressions, and mathematical functions.

You can change the definition to one of several commonly used expressions with the
Expression popup menu (see “The Expression popup menu”).

Special editing key combinations

These special mouse and key combinations are useful when editing a definitions:

<table>
<thead>
<tr>
<th>Key or key combination</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>double-click</td>
<td>Selects the entire identifier containing the cursor.</td>
</tr>
<tr>
<td>option-click a node</td>
<td>Inserts identifier of the node at the cursor position.</td>
</tr>
<tr>
<td>left-arrow ←, right-arrow →</td>
<td>Moves cursor one character left or right.</td>
</tr>
<tr>
<td>Up-arrow, down-arrow</td>
<td>Moves one line up or down.</td>
</tr>
<tr>
<td>Control+left-arrow, Control+right-arrow</td>
<td>Moves to the beginning or end of the next word or identifier.</td>
</tr>
<tr>
<td>Alt+Control+left-arrow, Alt+Control+right-arrow</td>
<td>Moves the cursor from the adjacent parenthesis to the next matching parenthesis, left or right.</td>
</tr>
</tbody>
</table>

If you also press Shift with any arrow movements, it selects the text between old and
new cursor positions for copy/paste operations, etc.

Parenthesis matching

Analytica expressions sometimes contain several levels of nested parentheses. To help
keep parentheses clear, when you place the cursor just to the right of a parenthesis, it
makes it and its matching parenthesis bold. This works for left or right parentheses,
square brackets, or curly brackets (used for comments). It helps you see whether you
have the right number and types of parentheses in complex expressions, without resorting
to counting.

The Alt+Control+arrow keys also help: For example, pressing Alt+Control+right-arrow when
the cursor is at A moves the cursor to B. Then pressing Alt+Control+left-arrow moves it
back again:

\[ \text{c} * ( - (\text{Ln}(\text{Uniform}(1f,1)) ) )^{(1/k)} \]

Comments in definitions

It is wise to document your models generously. Usually, it’s best to document what a
variable or function represents in its Description attribute, and also explain its algorithm
if it’s not obvious. For complex, multiline definitions, it’s also useful to insert comments
within the definition. Comments can also be used to disable portions of expressions
while debugging.
Enclose comments in curly brackets:

```
Variable X := -b*Sqrt(B^2 - 4*A*C)/A { Positive quadratic root }
```

You may insert a comment at any point in an expression where whitespace is allowed. Analytica ignores anything inside a comment when parsing or evaluating an expression. If you start a comment with "{" , then your comment cannot contain the "}" character within the comment.

It does not preserve comments in the cells of an edit table — so it’s not worth entering comments there.

**Identifiers**

To refer to the value of another variable, use its identifier. To place a variable’s identifier at the insertion point in the definition, do any of the following:

- If the variable is an input, select it from the **Inputs** popup menu.
- Type in the variable’s identifier. To see all nodes in the active diagram labeled by their identifiers (instead of their titles), select **Show By Identifier** from the **Object** menu (Control+y). (Note that entering Control+y a second time switches the diagram back to displaying the nodes by their titles.)
- Select **Paste Identifier** from the **Definition** menu and use the **Find** button or identifier menu items (see “Object Finder dialog”).
- If the definition is being edited from the **Attribute** panel, you can insert the identifier of a variable in the same module window by holding down the Alt key and clicking the node. The identifier of the clicked node will be inserted at the caret position. This shortcut isn’t available from the **Object** window or for nodes in different modules.

**Functions**

You can paste functions at the insertion point by doing either of the following:

- Select **Paste Identifier** from the **Definition** menu to open the **Object Finder** (see “Object Finder dialog”).
- Select the function from its library in the **Definition** menu (see “Using a function or variable from the Definition menu” on page 123).

**Syntax check**

After entering or editing a definition, press Alt-Enter or click the accept button to perform a syntax check of the revised definition and accept the changes.

Click the cancel button to cancel your changes.

The definition warning icon appears next to the definition if it is not syntactically correct. Click the icon to see a message about what may be wrong.
Creating or editing a definition

A definition’s syntax check may reveal syntax errors (see “Syntax error”). For example, if a definition contains text that is not an identifier, the following dialog box appears.

Automatically updating the diagram

After you give a variable a valid definition, the influence diagram containing that variable might change.

Cross-hatching disappears

Normally, any node whose definition is missing or invalid displays with a cross-hatch pattern:

After you enter a valid definition, the node becomes clear.

You can remove cross-hatching even from invalid variables by unchecking Show Undefined in the Preferences dialog from the Edit menu.

Arrow updating

After you enter or edit a definition, it ensures that the arrows going into the node to properly reflect its inputs: It adds an arrow from any extra variable you mentioned. It removes an arrow from any variable you didn’t use in the definition.
The Expression popup menu

Click `expr` to see the **Expression popup menu**. The Expression popup menu shows the type of the definition, which is an empty expression in the following figure.

Use this popup menu to change the definition to one of several common kinds of expressions. The entries in this menu depend on the class of the node being defined.

- **Expression**: Shows the definition as a mathematical expression, even if it was defined using the other expression types in this popup menu. See Chapter 10, "Using Expressions".
- **List**: Creates an ordered set of expressions or numbers. See “Creating an index”.
- **List of Labels**: Creates an ordered set of text labels. See “Creating an index”.
- **Sequence**: Creates a list of numerical values. See “Sequence (start, end, stepSize)".
- **Table**: Creates an array of numbers or expressions. See “Arrays and Indexes”.
- **Probability Table**: Creates an array defining probabilities (numbers or expressions) across the domain of a discrete (chance) variable. See "Probability table(): Probability Tables".
Chapter 8 Creating and Editing Definitions

Object Finder dialog

The Object Finder dialog lets you browse built-in functions, your own library functions, and all the objects in your model to insert into a definition. You can open the Object Finder in two ways:

- To insert the desired function or identifier at the cursor position in the definition, select Paste Identifier from the Definition menu, or
- To replace the entire definition with the desired function, select Other from the expr (Expression) menu.

Library popup menu

Contents of selected library

Parameters to selected function

Description of selected function

Find button for searching for model objects
Select the desired set or library from the **Library** menu:

These are the top items in the library menu:

- **Found objects**  Objects found from **Find** button (see below)
- **All Available**  All objects and functions, from model and built-in
- **All Modules**  Objects from all module in the models
- **Current Module**  Objects in the current module
- **Inputs**  Inputs to the selected node

Use the **Find** button to search for an object by its identifier or title

The **Found objects** library in the **Object Finder** dialog will then list all objects whose identifier or title matches in their first \( n \) characters (the \( n \) characters you type into the search box).

To use a function, identifier, or system expression in a definition, select it. For a function, enter the required parameters in the parameter fields.
Using a function or variable from the Definition menu

The Definition menu lists built-in libraries of functions, system variables, and operators, as well as any libraries you have added. It shows these as a hierarchical menu that so you can rapidly find what you need and paste it into the definition you are editing. To find and paste a function or other object from a library:

1. Move the cursor to the place in the definition that you want to insert a function or other item.
2. From the Definition menu, select the library you want, and then the function or other item.

Click OK to place the function, identifier, or expression in the definition.
Automatic checking for valid values

You can create an automatic check on the validity of the value of a variable by setting its \textit{check} attribute. For example, to check that the value of \texttt{Percent\_damage} is between 0 and 100, set its \textit{check} attribute:

\begin{align*}
\text{Check: } \texttt{Percent\_damage} &\geq 0 \text{ AND } \texttt{Percent\_damage} \leq 100
\end{align*}

If the \textit{check} attribute evaluates to False, whenever the variable is evaluated, it shows a warning dialog and the opportunity to edit the definition.

You can always view and edit the \textit{check} attribute in the \textit{Attribute} panel, if you open it below a diagram. If you want to view or edit it in \textit{Object} windows, you must first cause it to be shown:

1. Select Attributes from the Object menu to open the Attributes dialog. (For more see “Managing attributes”.)
2. Scroll down the attribute list and find **Check**.

3. Click **Check** once to select it, and a second time to add a check mark next to it. The check mark indicates that the attribute is displayed in the **Object** window.

4. Click **OK**.

Now the **check** attribute will appear in **Object** windows for all **variables**. You can also set it to appear for **functions** by repeating the steps above but selecting **Functions** from the **Class** menu in the **Attributes** dialog.

**Defining the check**

Either open the **Object** window for the variable, or open the **Attribute** panel below the diagram and select **Check** from the **Attribute** menu. Enter a Boolean (logical) expression in the **Check** field that will return true (1) if the value is acceptable, or false (0) if not. The expression should refer to the variable by its identifier or as **Self**. For example, to check that the value for the **Lifetime** of a car is more than 0 and less than 12 years, define the check as:

```
Check: (Lifetime > 0)And (Lifetime < 12)
```

or

```
Check: (Self > 0)And (Self < 12)
```

If the **Check** expression refers to another variable, it makes a dependency from the variable being checked to the variable mentioned. It will usually show an arrow from that variable.

**Triggering a check**

If a variable x has an input node, it performs the check whenever you change its input value (or definition) (see “Users of your model can then easily view and modify input variables, and view the results, without navigating the details of the model, unless they wish to.”). Otherwise, it performs the check each time it evaluates the checked variable, x — that is, when you first view a result for x or a variable on which x depends. If you view or compute a probabilistic value for x, it will warn if any sample value of x fails the check. More generally, if the value of the **Check** expression is an array, it will fail if any atom in the array is false (0). If you view first the mid value of x and then a probabilistic value, that causes two evaluations and so two checks.

If you change the definition of x or any variable on which it depends, **including** any variable mentioned in its **Check** expression, it will perform the check again next time you view x or a variable that depends on it.
If a check fails
If a check fails — evaluates to False — the warning dialog offers the option of editing the variable's definition, cancelling, or continuing. If you continue, it will not perform the check again unless you change the definition of the variable or a variable it depends on.

Custom error messages
The default warning when a check fails shows the **Check** expression. This is OK for modelers, but may be obscure for end users. If you call the `Error()` function (see “Error(message)” on page 368) in the check, it displays the message you pass to `Error()` instead of the default warning. Using this, you can craft a more helpful message. The warning gives the same options:

To disable checking
You can disable all value checking by unchecking **Check value bounds** in the **Preferences** dialog from the **Edit** menu (see “Preferences dialog”). This check box is checked by default.
This chapter shows you how to create a user interface containing input and output nodes for easy access for other people who may use your model.
For a complex model, you can make it easier to use, especially by other people, by creating a user interface. A user interface is simply a diagram containing input and output nodes. These inputs and outputs are selected variables that users may change (inputs) or view (outputs). By gathering input and output nodes into a single user interface diagram, users have quick access from a central window, even if the underlying variables may be located in other parts of the module hierarchy.

Input nodes allow the user to see and change the values of variables directly in a diagram. Input nodes may be a field to enter a number or text value, a button that opens an edit table or probability distribution, or a pulldown menu. Output nodes show atoms (single numbers or text values) in the diagram, and show a button for uncertain or array-valued variables, so that users can open tables or graphs with a single click.

Input and output nodes are a kind of alias node linked to the original node. Input and output nodes usually show the title and units of a variable to the left of the input or output field or button:

Users of your model can then easily view and modify input variables, and view the results, without navigating the details of the model, unless they wish to.

This diagram shows input nodes on the left side and output nodes on the right side. To see the details of the model, you would double-click the Details node to open up its diagram.

See Chapter 1, “Examining a Model.”

Using input nodes

An input node lets you, or your end user, see and easily change the value of a variable directly in the diagram, without opening an Attribute view or Object window (see “Browsing with input and output nodes”). In browse mode you can change only the values and definitions of input nodes.

An input node is an alias of a variable that you want to treat as an input to the model (see “An alias is like its original”).
Chapter 9  Creating Inputs and Outputs

Creating a choice menu

The type of definition of the original variable determines the appearance of the input node (see "The Expression popup menu"). If you want your users to be able to change the type of definition, instruct them on how to open an Attribute view or Object window and use the Expression popup menu.

Input field
A single number or text value (scalar) displays as an input field. You can have Analytica check if the input value is acceptable by using the Check attribute (see "Automatic checking for valid values"); the check is performed on input of a new value.

Input popup menu
A choice displays as an input popup menu. To create an input menu for an input node, see “Creating a choice menu”.

List
A list or list of labels displays as a List button (see “Creating an index”).

Edit table
An edit table displays as an Edit Table button (see “Viewing an array as an edit table”).

Probability distribution
A probability distribution displays a button with the name of the distribution (see "Defining a variable as a distribution").

Creating an input node
To create an input node from a variable:
1. Make sure you are in edit mode.
2. Select the variable.
3. Select Make Input Node from the Object menu. The input node will appear in the same diagram next to the selected node.
4. Move the input node to the location you want.
5. Adjust the size of the node.

Tip
To make several input nodes at once, select the nodes and then choose Make Input Node.

Creating a choice menu

For the classes of nodes that may be used for parametric analysis, such as decision and chance, the Expression popup menu includes the Choice option. The Choice option provides a way to offer the user a choice of selecting one or all values from a list.

Creating a menu from a list
If the original variable is already defined as a list of numbers or labels, create a popup menu to select from the list as follows:
1. Show the definition of the variable as a list, either in the Attribute view or the Object window.
2. Click the Expression popup menu and select the Choice option. Click OK to "Replace current definition with a Choice?" Click OK to "Replace current definition?"

3. The Object Finder dialog displays with parameter I=Self and n=0. Press OK.
   The definition field of the original variable now displays as a popup menu, and in browse mode, the input node displays as a popup menu. The original definition (list of numbers or labels) is now available as the domain of the variable — the possible outcomes. In the expression view, the popup menu displays as the Choice() function (see "Choice(i, n, inclAll)").

   **Tip**  
   To define Var1 as a popup menu of another variable Var2, that is defined as a list, select Choice from the Expression popup menu, and set the first parameter to I=Var2 in the Object Finder dialog.

   **Tip**  
   To hide the All option on the popup, enter inclAll=False as the third parameter in the Object Finder dialog.

**Creating a new definition**  
If a variable has no previous definition, when you select Choice from the Expression popup menu, a domain (possible outcomes) of List of labels is created, with one element in the list.

To change the domain to List of numbers, press the Domain popup menu and select List of numbers.

Edit the list of values as you would edit a list of labels or list of numbers (see "Editing a list").

*Note: The values in the domain are evaluated deterministically.*
Using output nodes

An output node gives you, or your end user, rapid access to a selected result in the model. You can use output nodes to focus attention on particular outputs of interest.

An output node displays a result value in the view style — i.e., whether table or graph, the indexes displayed, and the uncertainty view — last selected for display and saved with the model. It also shows the uncertainty view icon (see "Uncertainty views").

If the result is a single value (mid value or mean), it displays directly in the output field.

If the result is a table, the output node displays a Result button. Click the button to display the table or graph.

After you display the table or graph, you can use the result toolbar to change the view.

If the value of an output has not yet been computed, the Calc button appears in the node. Click the Calc button to compute and display the value.

Creating an output node

To create an output node from a variable:

1. Make sure you are in edit mode.
2. In a Diagram window, select the node of the variable for which you wish to create an output node.
3. Select Make Output Node from the Object menu. The output node will appear in the diagram next to the selected node.
4. Move the output node to the location you want.
5. Adjust the size of the node.

The view style of the output result — table or graph — will be the format you last set for it (see "Formatting Numbers, Tables, and Graphs").

Resizing controls

You can resize input and output nodes by dragging their corner handles, just like other nodes. But for these, its usually most convenient to deselect Resize centered from the Diagram menu so you can align them either along their right edges, or both edges.

You can also drag the left edge of the control field, button, or menu left or right to change its width. This is especially useful for choice menus when you may want to expand the width to be large enough for the widest menu option.

When using a pull-down menu containing long text values, you may wish to adjust the pull-down control as necessary to accommodate your longest text value. Input and output nodes contain text and graphics, in addition to the control itself. The node resizing handles that appear as small black squares at the corners of the node adjust the size of the bounding rectangle that holds all these items, but does not change the width of the control itself. To change the width of a control (a pull-down menu, textedit box, or button), position the mouse over the left edge of the control, depress the mouse button and drag the cursor to the left or right.
Input and output nodes and their original variables

The title and units of an input or output node are obtained from the original node. To edit them, edit the title and units of the original node (see "To edit an attribute"). If you edit the title or units of the original node, the input or output node's title or units changes to match the original.

By default, an input or output node shows its original node's title (label) in the original font, with no node outline or arrows. The node takes its color from its original node when the node is created. Later changes to the original node color do not change the color of the input or output node.

To change the appearance of an input or output node alone, use the Set Node Style and Show Color Palette options from the Diagram menu (see "Node Style dialog" and "Recoloring nodes or background"). When you use these options to change the appearance of an input or output node, its original node does not change. Similarly, using these options to change the appearance of an original node does not affect its previously created input or output node.

Using form modules

It is often helpful to group input and output nodes into a single diagram for easy access by model users. The form module makes it easy for you to create input and output nodes in the form by drawing arrows between the form and variables.

To create a form module

1. Make sure a diagram window is active with the edit tool selected.
2. Drag the module icon from the node toolbar and position it in the diagram.
3. Type in a title for the module — for example, User interface.
4. Open the Attribute panel at the bottom of the diagram window.
5. With the new form module still selected, press to open the Attribute popup menu, and select Class.
6. The class Module appears in the Attribute panel. Press to open a popup menu of module classes:

```
[ ] Model
[ ] Module
[ ] Module
[ ] Library
[ ] Library
[ ] Form
```

7. Select Form from the menu.

Creating input and output nodes in a form module

An input or output node is an alias to another variable in the model. Creating an input or output node is similar to creating an alias (see "Alias nodes"). To create a set of input and/or output nodes in the form module:

1. Adjust the diagram(s) on your screen so the form node and the source variables for the input or output nodes are all visible — they may be in the same or different diagrams.
2. In the toolbar, click \[ \rightarrow \] to enter arrow mode.

3. **To create an input node for variable X**, draw an arrow from the form node to X. It creates an input node for X inside the form module.

4. **To create an output node for variable Y**, draw an arrow from Y to the form node. It creates an output node for X inside the form module.

5. When you have finished creating input and output nodes, double-click the form node to open its diagram window.

6. In the toolbar, click \[ \text{ } \] to enter edit mode.

7. Rearrange and resize the input and output nodes for clarity. It is sometimes clearest to arrange the input nodes on the left side and the output nodes on the right side.

A form module is like any other module, except when you draw arrows into or out of a form module, it creates outputs or inputs, instead of normal alias nodes in the module. But, you can also create standard variables and modules inside a form. If you have too many nodes to fit comfortably in a single diagram, you may wish to organize them into additional modules (which need not be forms) to enclose related groups of inputs and outputs.

### Adding icons to nodes

You can add an icon to any node in a diagram. The **Icon** window contains an enlarged space that you can use for creating or editing an icon.

#### Opening the Icon window

To add an icon:

1. Make sure that the edit tool is selected.
2. Select the node that you wish to illustrate.
3. Choose **Edit Icon** from the **Diagram** menu to open the **Icon** window.
Adding icons to nodes

You can draw or edit the icon one pixel at a time using mouse clicks, or you can draw lines by holding down the mouse button as you drag the cursor.

- To make a dark pixel light or a light pixel dark, click the pixel.
- To draw a line or curve hold down the mouse button while you move the cursor. If the starting pixel of the line or curve is black the line or curve will be black; if the starting pixel of the line or curve is white the line or curve will be white.
- To set the node’s icon, click the Accept button.
- To restore the original icon in the window (or to clear the window if there was no previous icon), click the Revert button.

You can copy and paste an icon from one place in a model to another using the standard Copy (Control+c) and Paste (Control+v) commands. You can delete an icon from a node by selecting it and using the Cut (Control+c) command or the Delete key.

Adjust the size of the node as necessary to show the icon and title.
Chapter 9 Creating Inputs and Outputs

Graphics, frames, and text in a diagram

Adding graphics  You can add a graphic image created in another application to any node or to the diagram background. Both color bitmaps and PICT graphics can be pasted in.

To paste in a graphic:
1. Copy (Control+c) the graphic to the clipboard from within a graphics application.
2. Make sure that the edit tool is selected in Analytica.
3. Select the node or the diagram window where you want the graphic to appear.
4. Paste (Control+v) the graphic from the clipboard.

When you paste a graphic into the diagram window, a special node of class picture is created. Picture nodes can be placed on top of variable, module, and function nodes.

To remove a graphic, select it and press Delete, or choose Clear from the Edit menu.

Adding a frame  You can create a rectangular frame for nodes in a diagram in either of the following ways:

- Paste a graphic into the diagram window to create a picture node, then delete the graphic. This leaves a blank picture node. Use the Node Style dialog box (see “Node Style dialog”) to display the border of the node. Other nodes can be placed on top of this node.

- Create a decision node and leave the title blank. Give it a definition of 0 (or any number) to remove the cross-hatch pattern. Use the Node Style dialog box (see “Node Style dialog”) to hide the label and fill color. Create this frame first, then create the nodes to be framed and place them in the frame. If you create a framing decision node after you create the nodes to be framed, the nodes will be “under” the framing decision node; they will be visible, but you will not be able to select them. To place the decision node underneath the other nodes, select the decision node while in edit mode, right mouse click and select the Send to Back command from the pop-up menu.

- Create a text node by dragging a text node from the text button on the toolbar. Use the Node Style dialog box (see “Node Style dialog”) to add a fill color and border to the node.

Adding text  To add text to a diagram, drag a text node from the text button on the toolbar to the diagram and enter the desired text. This creates a new node with a special class text. Use the handles to resize the node, and use the Node Style dialog box (see “Node Style dialog”) to change the font or to change the background from transparent to filled.

Models in XML file format

By default, Analytica 4.0 saves models in its own slot-filler format. You can also save Analytica models in XML format. XML format lets you use a variety of applications that work with XML to read and edit the model files.

The format for saving models  Analytica 4.0 remembers which file format a model used and will save models in the same format. Hence, models created in earlier releases of Analytica for Windows or
Macintosh will continue to use the old format. You can override that format by (un)checking Save in XML Format in the Save as dialog selected from the File menu.

Compatibility with older releases
If you want to share models created in Analytica 4.0 with users who are using earlier releases, you should uncheck the Save in XML Format check box in the Save as dialog. You will also need to avoid using any of the new syntax or functions introduced in Analytica 4.0 and described in the Upgrade Guide.

Sample old file format
Here is part of a sample model file in the old "slot filler" format:

```
{ From user Richard Morgan, Model Sample_old_file_format --
at Jun 1, 2007 3:56 PM}

```
Hyperlinks in model documentation

Any description, or other text attribute of a variable or other object, can contain a hyperlink to any Web page. This is useful for linking to detailed explanations, data, or references for a model, or even to related downloadable Analytica models. In browse mode, hyperlinks appear conventionally underlined in blue. When you click a hyperlink, your computer will show the indicated web page in your default web browser.

To define or edit a hyperlink, enter edit mode, and use a standard HTML link syntax of the form

```html
<a href="http://www.lumina.com">Click here</a>
```

When you switch to browse mode the HTML code will display as a hyperlink.

Chapter 10

Using Expressions

This chapter tells you how to:

• Write values, including numbers, Booleans, and text values
• Define expressions using arithmetic, logical, and comparison operations, and functions
• Select common functions that operate on numbers and text values
This chapter describes the building blocks for creating and editing expressions to define variables: numbers, operators and mathematical functions.

**Numbers**

The following formats are all valid for entering numbers:

<table>
<thead>
<tr>
<th>Number Format</th>
<th>Examples</th>
</tr>
</thead>
<tbody>
<tr>
<td>Integers</td>
<td>2, 10, 1234, -16</td>
</tr>
<tr>
<td>Decimals</td>
<td>32.5, .0002, 0.000012345</td>
</tr>
<tr>
<td>Suffix</td>
<td>250K, 10.5M, 10.5m, 22%</td>
</tr>
<tr>
<td>Exponential form</td>
<td>5.3e+11, 1e20, 4.5632e-25</td>
</tr>
</tbody>
</table>

- The signed integer after the e is an exponent that denotes a power of ten. For example:
  
  $5e4 = 5 \times 10^4 = 50,000$

  $4.3e-3 = 4.3 \times 10^{-3} = 0.0043$

- A character suffix denoting a power of ten is a convenient way to express very large or small numbers. For example:

  $50K \rightarrow 50,000$

  $1.5m \rightarrow 0.0015$

The character suffixes are the same as used in the default output number format (see the table on page 87).

<table>
<thead>
<tr>
<th>Power of 10</th>
<th>Suffix</th>
<th>Prefix</th>
<th>Power of 10</th>
<th>Suffix</th>
<th>Prefix</th>
</tr>
</thead>
<tbody>
<tr>
<td>3</td>
<td>K</td>
<td>Kilo</td>
<td>-2</td>
<td>%</td>
<td>percent</td>
</tr>
<tr>
<td>6</td>
<td>M</td>
<td>Mega or Million</td>
<td>-3</td>
<td>m</td>
<td>milli</td>
</tr>
<tr>
<td>9</td>
<td>B</td>
<td>Billion</td>
<td>-6</td>
<td>µ</td>
<td>micro (mu)</td>
</tr>
<tr>
<td>9</td>
<td>G</td>
<td>Giga</td>
<td>-9</td>
<td>n</td>
<td>nano</td>
</tr>
<tr>
<td>12</td>
<td>T</td>
<td>Tera or Trillion</td>
<td>-12</td>
<td>p</td>
<td>pico</td>
</tr>
<tr>
<td>15</td>
<td>Q</td>
<td>Quad</td>
<td>-15</td>
<td>f</td>
<td>femto</td>
</tr>
</tbody>
</table>

**Tip**

The character suffixes m (10^{-3}) and M (10^6) are distinct. This is the only situation in which the case of a letter makes any difference for input to Analytica. For example, you can use k and K interchangeably.

**Range**

Analytica can represent numbers between $10^{-308}$ and $9 \times 10^{307}$. 
Numbers out of range  When a calculation results in a number whose absolute value is less than the smallest number that can be represented, Analytica rounds the number to 0 (zero) without warning. For example:

\[ \frac{1}{10^{1000}} \rightarrow 0 \]

**INF (infinity)**  When a calculation results in a number whose absolute value is greater than the largest that can be represented, Analytica displays it as INF or -INF, for positive or negative infinity. For example:

\[ 10^{1000} \rightarrow INF \]
\[ -1 \times 10^{1000} \rightarrow -INF \]
\[ 1/0 \rightarrow INF \]

You can enter INF as a value in an expression. Analytica can perform some computations with INF, such as:

\[ INF + 10 \rightarrow INF \]
\[ INF/0 \rightarrow INF \]
\[ 10 - INF \rightarrow -INF \]

Other computations with INF, such as difference and ratio, give results that are ill-defined and return NAN (Not A Number):

\[ INF - INF \rightarrow NAN \]
\[ INF/INF \rightarrow NAN \]

A NAN may be detected in an expression using the `IsNaN()` function. See page 148.

### Null, Undefined, NAN, and INF

Analytica may return the following system constants:

<table>
<thead>
<tr>
<th>Constant</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>Undefined</td>
<td>A value has never been defined or is uncomputed.</td>
</tr>
<tr>
<td>Null</td>
<td>There is no such item.</td>
</tr>
<tr>
<td>NAN</td>
<td>The result is numeric, but not a real number or infinity; (e.g., <code>Sqrt(-1)</code> or <code>0/0</code>).</td>
</tr>
<tr>
<td>INF</td>
<td>Infinity or a real number larger than can be represented (e.g., <code>1/0</code>).</td>
</tr>
<tr>
<td>-INF</td>
<td>Negative infinity or a number smaller than can be represented (e.g., <code>-1/0</code>).</td>
</tr>
</tbody>
</table>

Functions such as `Slice()`, `Subscript()`, `Subindex()`, and `MDTable()` may return Null—for example, when trying to `Slice()` out the \( n \)th element of an array whose index has less than \( n \) elements, for example:

\[ \text{Index I := 1..5} \]
\[ \text{Slice(I^2, I, 6) \rightarrow Null} \]

Undefined may result from attempting to use the value of an optional parameter in a user-defined function that hasn't been provided by the caller. Undefined and Null are treated as the same in evaluation of expressions.

You can test for Null using the standard = or <> operators, or you can use `IsUndef()`.

### Precision

The maximum internal precision of numbers is 15 significant digits.

Some calculations, especially those that involve small differences between numbers, may result in less precision than the maximum.
Chapter 10 Using Expressions

Text values

You specify a text value by enclosing text in single quotes, or in double quotes, for example:

'A', "A25", ‘A longish text - with punctuation.’

A text value can contain any character, including any digit, comma, space, and new line. To include a single quote(‘) or apostrophe, type two single quotes in sequence, such as:

'Isn’t this easy?’

The resulting text will contain only one apostrophe character. Or you can enclose the text value in double quotes:

"Don’t do that!"

Similarly, if you want to include double quotes, enclose the text in single quotes:

‘Did you say "Yes"?’

You can enter a text value directly as the value of a variable, or in an expression, including as an element of a list (see “Creating an index” and “List vs. list of labels”) or edit table (see “Creating an array with an edit table”). Analytica displays text values in results without the enclosing quotes. Also see “Converting a number to text”.

Boolean or logical values

There are two Boolean or logical values — True and False. You can specify a Boolean value in an expression as False or True, or, equivalently, as the numbers, 0 or 1, respectively. For example:

False or True → True
1 and 0 → False
1 or 0 → True

Analytica treats every nonzero number as True. For example:

2 And True → True

Analytica displays Boolean results as 0 or 1, by default. To display them as False or True, change the format of the definition or result to Boolean (see “Number formats”).

Operators

An operator is a symbol, such as a plus sign (+), that represents a computational operation or action such as addition or comparison. Analytica includes the following sets of standard operators.

Arithmetic operators

The arithmetic operators apply to numbers and produce numbers.

<table>
<thead>
<tr>
<th>Operator</th>
<th>Meaning</th>
<th>Examples</th>
</tr>
</thead>
<tbody>
<tr>
<td>+</td>
<td>plus</td>
<td>3+2 → 5</td>
</tr>
<tr>
<td>-</td>
<td>minus</td>
<td>3-2 → 1</td>
</tr>
</tbody>
</table>
Chapter 10  Using Expressions

Operators

Comparison operators

<table>
<thead>
<tr>
<th>Operator</th>
<th>Meaning</th>
<th>Examples → (1 = true, 0 = false)</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt;</td>
<td>less than</td>
<td>2&lt;2 → 0 '&lt;A'&lt; 'B' → 1</td>
</tr>
<tr>
<td>&lt;=</td>
<td>less than or equal to</td>
<td>2&lt;=2 → 1 'ab'&lt;= 'ab' → 1</td>
</tr>
<tr>
<td>=</td>
<td>equal to</td>
<td>100=101 → 0 'AB' = 'ab' → 0</td>
</tr>
<tr>
<td>&gt;=</td>
<td>greater than or equal to</td>
<td>100&gt;=1 → 1 'ab'&gt;= 'cd' → 0</td>
</tr>
<tr>
<td>&gt;</td>
<td>greater than</td>
<td>1&gt;2 → 0 'A'&gt; 'a' → 1</td>
</tr>
<tr>
<td>&lt;&gt;</td>
<td>not equal to</td>
<td>1&lt;&gt;2 → 1 'A'&lt;&gt; 'B' → 1</td>
</tr>
</tbody>
</table>

Alphabetic ordering of text values

The comparison operators, >, >=, =, and <, compare the alphabetic ordering based on ASCII coding of two text values. For example,

‘Analytica’ < ‘Excel’ → 1 (true)

Using the numerical (ASCII) representation of the characters, means:

1. Digits precede (are smaller than) letters, so

   9 < 'A' → 1 (True)

2. Uppercase letters precede lowercase letters. If you want to alphabetize without regard to case, first use TextUpperCase (or TextLowerCase) to convert all letters to the same case.

   ‘Analytica’ > ‘excel’ → 0 (False)
   TextUpperCase(‘Analytica’) < TextUpperCase(‘excel’) → 1 (True)

3. Letters with accents, umlauts, cedillas, ligatures, and other decoration come after undecorated letters, hence alphabetic ordering may be different from what you expect.

SortIndex(a, f) sorts text values in a using the same ordering scheme. But, Rank() works only on numerical values, and does not rank text values.

Comparison operators apply to numbers and text values and produce Boolean values.

Comparison operators

<table>
<thead>
<tr>
<th>Operator</th>
<th>Meaning</th>
<th>Examples</th>
</tr>
</thead>
<tbody>
<tr>
<td>&gt;</td>
<td>to the power of</td>
<td>3^2 → 9</td>
</tr>
<tr>
<td>&lt;=</td>
<td>divided by</td>
<td>3/2 (= 3/2) → 1.5</td>
</tr>
<tr>
<td>&gt;=</td>
<td>(fractional exponent)</td>
<td>4^.5 (= 4^1/2) → 2</td>
</tr>
<tr>
<td>&lt;</td>
<td>multiplied by</td>
<td>3*2 → 6</td>
</tr>
<tr>
<td>&lt;&gt;</td>
<td></td>
<td>1 (true)</td>
</tr>
</tbody>
</table>

Digits precede letters, so

9 < 'A' → 1 (True)

Uppercase letters precede lowercase letters. If you want to alphabetize without regard to case, first use TextUpperCase (or TextLowerCase) to convert all letters to the same case.

‘Analytica’ > ‘excel’ → 0 (False)
TextUpperCase(‘Analytica’) < TextUpperCase(‘excel’) → 1 (True)

Letters with accents, umlauts, cedillas, ligatures, and other decoration come after undecorated letters, hence alphabetic ordering may be different from what you expect.

SortIndex(a, f) sorts text values in a using the same ordering scheme. But, Rank() works only on numerical values, and does not rank text values.
Logical operators

The logical operators apply to Boolean values and produce Boolean values.

<table>
<thead>
<tr>
<th>Operator</th>
<th>Meaning</th>
<th>Examples</th>
</tr>
</thead>
<tbody>
<tr>
<td>\texttt{b1 AND b2}</td>
<td>true if both \texttt{b1} and \texttt{b2} are true, otherwise false</td>
<td>\texttt{1 AND 20&lt;2} → 0</td>
</tr>
<tr>
<td>\texttt{b1 OR b2}</td>
<td>true if \texttt{b1} or \texttt{b2} or both are true, otherwise false</td>
<td>\texttt{0 OR 1&lt;2} → 1</td>
</tr>
<tr>
<td>\texttt{NOT b}</td>
<td>true if \texttt{b} is false, otherwise false</td>
<td>\texttt{NOT (2&lt;3)} → 0</td>
</tr>
</tbody>
</table>

Scoping operator (::)

Since new versions of Analytica introduce new functions that did not exist in previous releases of Analytica, it is possible that a model created in a previous release may contain a variable or other object with the same identifier as a new built-in variable or function. In this situation, an identifier name appearing in an expression may be ambiguous.

Prepending :: to the name of a built-in function causes the reference to always refer to the built-in function. Otherwise, the identifier will refer to the user’s variable or function. With this convention, existing models are not changed by the introduction of new built-in functions.

Example

Suppose a model from an older release of Analytica contains the user-defined function \texttt{Irr(Values,I)}. Then

\[
\begin{align*}
\text{Irr(Payments,Time)} & \quad \text{User’s Irr function} \\
::\text{Irr(Payments,Time)} & \quad \text{The built-in function}
\end{align*}
\]

Operator binding precedence

A precedence hierarchy resolves potential ambiguity when evaluating operators and expressions. The precedence for operators, from most tightly bound to least tightly bound is:

1. parentheses ()
2. function calls
3. \texttt{Not}
4. \texttt{@I, \textbackslash A, \textbackslash[I]A, #R.}
5. \texttt{A.I}
6. \texttt{A[I=x]}
7. \texttt{Attrib of Obj}
8. \texttt{^}
9. \texttt{-} (unary, negative)
10. \texttt{*, /}
11. \texttt{+, -} (binary, minus)
12. \texttt{m..n}
13. \texttt{<, >, <=, >=, =, <>}
14. And, Or

15. & (text concatenation)

16. :=

17. If ... Then ... Else, Ifonly ... Then ... Else, Ifall ... Then ... Else

18. Sequence of statements separated by semicolons, sequence of elements or parameters separated by commas

Within each level of this hierarchy, the operators bind from left to right (left associative).

**Examples**

The following arithmetic expression:

\[ \frac{1}{2} \times 3 - 3^2 + 4 \]

is interpreted as:

\[ \left( \frac{1}{2} \times 3 \right) - (3^2) + 4 \]

The following logical (Boolean) expression:

\[ \text{If } a \text{ and } b > c \text{ or } d + e < f \text{ and } g \text{ Then } x \text{ Else } y + z \]

is interpreted as:

\[ \text{If } ((a \text{ and } (b > c)) \text{ or } ((d + e) < (f \text{ and } g))) \text{ Then } x \text{ Else } (y + z) \]

### IF a THEN b ELSE c

This conditional expression returns \( b \) if \( a \) is true (1) or \( c \) if \( a \) is false (0), for example:

```plaintext
Variable A := 1M
Variable B := 1
IF X > Y THEN X ELSE Y
```

will return the larger of \( X \) and \( Y \).

It is possible to omit the ELSE clause:

```plaintext
IF X > Y THEN X
```

But, if the condition is false, it will give a warning. If you ignore the warning, it returns NULL.

Conditional expressions get more interesting when they work on arrays. See “IF a THEN b ELSE c with arrays”.

### Functions

Analytica provides a large number of built-in functions for performing mathematical, array, statistical, textual, and financial computations. There are also probability distribution functions for uncertainty and sensitivity analysis. Other more advanced or specialized functions are described in Chapter 13, “Other Functions.” The Enterprise edition of Analytica also includes functions for accessing external ODBC data sources. Finally, you can write and use your own user-defined functions (see “Building Functions and Libraries”)
Position-based function calls

The conventional position-based syntax to call a function has this form:

\[ \text{FunctionName}(\text{param1}, \text{param2}, \ldots) \]

The function name is followed by a comma-delimited list of parameters enclosed between parentheses. In most cases, parameters can themselves be expressions built out of constants, variable names, operators, and function calls. Here are some simple examples of expressions involving functions.

\[
\begin{align*}
\text{Exp}(1) & \rightarrow 2.718281828459 \\
\text{Sqrt}(3^2 + 4^2) & \rightarrow 5 \\
\text{Round}(2\times\pi) & \rightarrow 6 \\
\text{Mod}(X, 3) & \rightarrow 1 \quad \text{where } X \rightarrow 7 \\
\text{Pmt}(8\%, 30, -1000) & \rightarrow $88.83 \\
N \times \text{Sum}(w\times w, J) & \\
\text{Normal}(500,100) & \\
\end{align*}
\]

Name-based function calls

Analytica also offers name-based parameter calling for most functions with multiple parameters.

Math functions

These functions can be accessed under the Definition menu Math command, or in the Object Finder dialog box, Math library.

Abs(x) Returns the absolute value of x.

\[
\begin{align*}
\text{Abs}(180) & \rightarrow 180 \\
\text{Abs}(-210) & \rightarrow 210 \\
\end{align*}
\]

Ceil(x) Returns the smallest integer that is greater than or equal to x.

\[
\begin{align*}
\text{Ceil}(3.1) & \rightarrow 4 \\
\text{Ceil}(5) & \rightarrow 5 \\
\text{Ceil}(-2.9999) & \rightarrow -2 \\
\text{Ceil}(-7) & \rightarrow -7 \\
\end{align*}
\]

Floor(x) Returns the largest integer that is smaller than or equal to x.

\[
\begin{align*}
\text{Floor}(2.999) & \rightarrow 2 \\
\text{Floor}(3) & \rightarrow 3 \\
\text{Floor}(-2.01) & \rightarrow -3 \\
\text{Floor}(-5) & \rightarrow -5 \\
\end{align*}
\]

Round(x) Returns the value of x rounded to the nearest integer.

\[
\begin{align*}
\text{Round}(1.8) & \rightarrow 2 \\
\text{Round}(-2.8) & \rightarrow -3 \\
\text{Round}(1.499) & \rightarrow 1 \\
\text{Round}(-2.499) & \rightarrow -2 \\
\end{align*}
\]

Exp(x) Returns the exponential of x — that is, ex must not be greater than 709.

\[
\begin{align*}
\exp(5) & \rightarrow 148.4 \\
\exp(-4) & \rightarrow 0.01832 \\
\end{align*}
\]

Ln(x) Returns the natural logarithm of x, which must be positive.

\[
\begin{align*}
\text{Ln}(150) & \rightarrow 5.011 \\
\text{Ln}(\exp(5)) & \rightarrow 5 \\
\end{align*}
\]

Logten(x) Returns the logarithm to the base 10 of x, which must be positive.

\[
\begin{align*}
\text{Logten}(180) & \rightarrow 2.255 \\
\text{Logten}(10 \times 30) & \rightarrow 30 \\
\end{align*}
\]

Sqr(x) Returns the square of x.
Sqr(5) → 25
Sqr(-4) → 16

Sqrt(x) Returns the square root of x, which must be positive or zero.
Sqrt(25) → 5

Mod(x, y) Returns the remainder (modulus) of x/y.
Mod(7,3) → 1
Mod(12,4) → 0
Mod(-14,5) → -4

Factorial(x) Returns the factorial of x, which must be between 0 and 170.
Factorial(5) → 120
Factorial(0) → 1

If x is not an integer, x is rounded to the nearest integer before taking the factorial.

Cos(x), Sin(x), Tan(x) Returns the cosine, sine, and tangent of x, x assumed in degrees.
Cos(180) → -1
Cos(-210) → -0.866
Sin(30) → 0.5
Sin(-45) → -0.7071
Tan(45) → 1

Arctan(x) Returns the arctangent of x in degrees.
Arctan(0) → 0
Arctan(1) → 45
Arctan(Tan(45)) → 45

See also "Arccos(x), Arcsin(x), Arctan2(y, x)" on page 213.

Degrees(r), Radians(d) Degrees gives degrees from radians, and radians gives radians from degrees:
Degrees(Pi/2) → 90
Degrees(-Pi) → -180
Radians(-90) → -1.57079633
Radians(180) → 3.141592654

Numbers and text

Converting a number to text If you apply the & operator or JoinText() to numbers, they convert the numbers to text values, using the number format specified for the variable or function in whose definition they appear. You can use this effect to convert ("coerce") numbers into text values, for example:

123456789 & '' → '123.5M'
123456789 & '' → '$123,456,789.00'
'The date is: ' & 38345 → 'The date is: Thursday, December 25, 2008'

Tip The actual result depends on Number Format setting for the variable or function in whose definition the expression appears. The first example assumes the default Suffix format. The second assumes Fixed Point format, with currency and thousands separators.
checked, and 2 decimal digits. The third assumes the Long Date format. Use the Number format dialog on the Result menu to set the formats.

---

### Converting text to a number

You can use the `Evaluate()` function to convert a text representation of a number into an actual number, for example:

\[
\text{Evaluate('12350')} \rightarrow 12.35K
\]

`Evaluate()` can convert any number format that Analytica can handle in an expression — and no others. Thus, it can handle decimals, exponent format, dates, true or false, a 'S' at the start of a number (which it ignores), and letter suffixes, like 'K' and 'M'. (See “Evaluate(t)”.)

An alternative method, for converting text to a number is to use the Coerce Number qualifier on a user-defined function. (See “Parameter qualifiers”.) For example, you could define a user-defined function such as:

\[
\text{ParseNum}(X: \text{Coerce Number}) := X
\]

### Datatype functions

Non-array values in Analytica may be numbers, text, or the special value `undefined` (and its equivalent `null`). The functions in this section, found on the Special sub-menu of Definition, can be used to determine the value type.

#### Isnumber(x)

Returns True if \( x \) is numeric, including INF or NAN

- `IsNumber(0)` → True
- `IsNumber(0/0)` → True
- `IsNumber(INF)` → True
- `IsNumber('hi')` → False
- `IsNumber(5)` → True
- `IsNumber('5')` → False
- `IsNumber(NAN)` → True

#### IsText(x)

Returns True if \( x \) is a text value.

- `IsText(7)` → False
- `IsText('hello')` → True
- `IsText('7')` → True

#### IsNaN(x)

Returns True if \( x \) is "not a number," i.e. `NAN`, `INF` and a regular number do not qualify, nor does a text or NULL.

- `0/0` → `NAN`
- `IsNaN(0/0)` → True
- `IsNaN(5)` → False
- `IsNaN(INF)` → False
- `IsNaN('Hello')` → False

#### x = NULL

To test if \( x \) is NULL.

#### Isundefined(x)

Returns True if \( x \) is either of the special values `undefined` or `null`. Equivalently, returns False if \( x \) is a number or a text value.
The value **Undefined** displays as a blank in a result table and generally indicates that a value is unavailable or hasn't been computed. For backward compatibility with releases of Analytica, this can also be used to detect Null.

The special value **undefined** cannot be directly entered in an expression. However, it may result from the evaluation of certain Analytica expressions. For example, the **Subindex()** function returns Null if the given value is not found.

```
Isundef('hello') → False
Isundef(5) → False
Isundef(0/0) → False
Isundef(1/0) → False
Isundef(Subindex(Time*2,1000,Time)) → True
```

*Note:* In the last example, **Time*2** does not contain the value **1000**, so **Subindex()** returns Null.

**TypeOf(x)**

Returns the type of expression x as a text value, usually one of "Number", "Text", "Reference", or "Null".

**Warnings**

Warnings may occur during evaluation, for example when trying to take the square root of a negative number or divide by zero, for example:

```
Variable X := Sequence(-2, 2)
Variable Y := Sqrt(X)
```

This **Warning** dialog gives you the option to ignore this and future warnings. If you select **Ignore Warnings**, Y yields:

```
Y → [NAN, NAN, 0, 1, 1.414]
```

The **NAN** (Not A Number) values may be propagated further into a model.

Analytica displays warning conditions detected while evaluating an expression only if the resulting value assigned to a variable contains an explicit error. In the following example, the errant NAN does not appear in the result, so it does not display a warning:

```
Variable Z := IF X<0 THEN 0 ELSE Sqrt(X)
Z → [0, 0, 0, 1, 1.414]
```

Because **(x<0)** evaluates to an array containing both True (1) and False (0) values, the expression will evaluate **Sqrt(X)**, and generate **NAN** as for **Y** above. But, the conditional means that resulting value for **Z** contains no **NANs**, and so Analytica generates no warning when **Z** is evaluated.

You can also make use of the return value, even if it might be errant, as in the following example:

```
VAR x := Sqrt(y);
```
IF IsNaN(x) THEN 0 ELSE x

The commonly encountered conditions of "subscript or slice value out of range" are
warnings with the return value of Null, for example:

Index I := 1..5
Slice(I^2, I, 6) → Null
This chapter introduces how to define and work with arrays and indexes. In particular, it explains Intelligent Arrays™, Analytica’s powerful and convenient features for working with multidimensional arrays.
The value of a variable may be an atom — a single number, Boolean, text value, or reference — or it may be an array — a collection of such values, viewable as a table with one or more dimensions. The ease and flexibility with which you can create, operate with, and display multi-dimensional arrays is the source of much of the power of Analytica for creating and managing large models. Each dimension of an array is identified by an index variable. You can extend a dimension simply by adding elements to its index. Or you can add a dimension to an array variable. These changes to dimensions will automatically carry through the rest of the model, often with no need to make other modifications.

There are some subtleties to the effective use of arrays. Your past experience with spreadsheets or programming languages may actually mislead you about how best to use arrays in Analytica. So, if you plan to use arrays in your models, we suggest that you first read the following sections, “Introduction to arrays” and “Operations on arrays”. The rest of this chapter gives the details on how to create index variables, how to use edit tables to create array values, and how the arithmetic, comparison, logical, and conditional operators work with arrays. “More Array Functions”, describes the special functions that create and operate on arrays.

Introduction to arrays

What is an array? An array is a collection of values that you can view as a table or graph. An array has one or more dimensions, which may appear as the row headers or column headers of a table. For example, the value of variable $\text{Fuel price per gallon}$ is a one-dimensional array indexed by $\text{Car type}$ with two values, $2.70$ for the small car (which uses regular gasoline) and $2.90$ for the large car (which uses premium gasoline):

$\text{Maintenance cost}$ is a two-dimensional array, indexed by $\text{Car type}$ and by $\text{Year}$:

The small car is cheap to maintain initially, but it gets more expensive than the large car after three years as its components start to wear out and need replacing.
Tip

You can swap the rows (Car_type) and columns (Year) by using the row or column popup menus (see “Index selection”).

Intelligent Arrays™ refers to the full set of features in Analytica for handling array abstraction. See “Intelligent Arrays™” for more information.

What is an index?

Each dimension of an array is identified by an index variable. The index variable holds the possible values — a list of numbers or a list of labels. In the examples above, Car_type is a list of labels, “small car” and “large car.” Year is a list of numbers.

To create an index, see “Creating an index”.

Before creating an array, it is usually best to create the indexes for the array’s dimensions. An index may be used in multiple arrays. When building a model that will use several multidimensional arrays, a key task is to define the indexes.

Index variables in a diagram

This diagram of a Car_cost_model includes the variables described above. The two indexes appear as purple parallelograms:

Fuel_price_per_gallon is the destination of an arrow from Car_type because it is defined as an array indexed by Car_type. Similarly, Maintenance_cost has arrows from Car_type and from Year, because it is indexed by both.
Tip
By default, Analytica does not show arrows to and from index variables. This often makes diagrams simpler by avoiding excessive numbers of arrows. But, you can display these arrows, as above, by checking Show arrows to/from Indexes in the Diagram Style dialog from the Diagram menu (see "Diagram Style dialog").

Viewing an array as an edit table
An edit table looks similar to a result table with the difference that you can edit the value of each cell, and sometimes also its index values. If you select a variable defined as an edit table and click the edit definition button, you will see its edit table.

Miles_per_gallon

To create or edit an array with an edit table, see “Creating an array with an edit table”.

Two sources of array value
When you evaluate a variable and its Result window shows an array value, there are two possible sources. A variable will have an array value if:

- It is defined as an array using an edit table, or
- It is defined as an expression calculated from one or more other array-valued variables.

Array abstraction
Analytica performs operations on arrays without your needing to explicitly identify or iterate over the dimensions of each array. When you use variables in expressions, you only need to refer explicitly to dimensions that are relevant to the operations being performed. If the actual values involve dimensions other than those that appear in your expressions, Analytica automatically abstracts over those dimensions with no extra effort on your part.

Because array abstraction automatically takes care of most iteration over arrays, Analytica expressions seldom contain explicit looping constructs. Individual expressions involving multi-dimensional arrays can be very simple, while in other languages the same operations would require multiple nested loops over the non-relevant dimensions.

Designing a model often requires you to make hard trade-offs between computational complexity, which dimensions to include, and the degree of detail. Spreadsheets and other programming languages force you to make these decisions early before you have implemented your algorithms and obtained the information that is relevant for making these trade-offs. The automatic management of dimensionality provided by array abstraction makes it easy for you make these trade-offs late in the model building process.
Chapter 11  Arrays and Indexes

Operations on arrays

Arithmetic operations and simple functions generalize straightforwardly when they are applied to arrays, according to the dimensions of the arrays. This section gives some simple examples.

Operation on a scalar and an array

An operation applied to a scalar and an array results in an array of the same shape, applying the scalar operation to each element in the array.

```
Miles_per_gallon : Table( Car_type, Miles_per_year ) ( 35, 25 )
Gallons_per_year: Miles_per_year / Miles_per_gallon
```

The result of an operation (division in this case) combining a scalar and an array is a result array with the same index(es) as the original array:

```
Fuel_cost_per_year: Fuel_price_per_gallon * Gallons_per_year
```

Both `Fuel_price_per_gallon` and `Gallons_per_year` are arrays with the same index, `Car_type`. The result is an array also indexed by `Car_type`, containing the value obtained by multiplying the corresponding elements of each array:

Operation on two arrays with the same indexes

An arithmetic operator applied to two arrays with the same indexes creates another array with the same indexes. Analytica applies the operator to pairs of corresponding elements.

```
Fuel_cost_per_year:
Fuel_price_per_gallon * Gallons_per_year
```

Operation on a one- and two-dimensional array

An arithmetic operator applied to a one-dimensional array and a two-dimensional array, that have one index in common, creates another two-dimensional array with the same two indexes.

```
Op_cost_per_year:
Fuel_cost_per_year + Maintenance_per_year
```
Operating_cost_per_year is the sum of a one dimensional variable indexed by Car_type and a two-dimensional variable indexed by Car_type and Year. The result is a two-dimensional array indexed by both indexes:

```
<table>
<thead>
<tr>
<th>Car_type</th>
<th>Year 1</th>
<th>Year 2</th>
<th>Year 3</th>
<th>Year 4</th>
<th>Year 5</th>
</tr>
</thead>
<tbody>
<tr>
<td>small car</td>
<td>$1071</td>
<td>$1371</td>
<td>$1271</td>
<td>$1771</td>
<td>$2171</td>
</tr>
<tr>
<td>large car</td>
<td>$1860</td>
<td>$1880</td>
<td>$1860</td>
<td>$1880</td>
<td>$2080</td>
</tr>
</tbody>
</table>
```

Each Car_type (row) in the result uses the fuel cost and maintenance cost for the corresponding Car_type. Each Year (column) uses the same annual fuel cost, which does not change by year, and the corresponding maintenance cost, which does change by year.

Changing the above table to a graph, using the graph button, shows:

The graph shows how the operating costs of the small car are less than the costs of the large car in the first three years and grow to be larger in the fifth year, crossing over just after the fourth year.

**Summing over an index variable**

The Sum() function sums an array over one index, giving a result without that index.

```
Total_operating_cost: Sum(Operating_cost_per_year, Year)
```

This operation sums Operating_cost_per_year over the Year dimension, producing a result indexed only by the Car_type dimension:
Tip

The expression does not need to mention any other possible indexes, such as Car_type.

Because the Sum() function eliminates one index of an array, it is called an array-reducing function. Analytica includes several array-reducing functions (see “Array-reducing functions”).

An arithmetic operator applied to two one-dimensional arrays with different indexes creates a two-dimensional array with both indexes.

Miles_per_year is redefined as a list (see “Create a list”):

Miles_per_year: [5000, 10K, 15K]

A list is a one-dimensional array that is indexed by itself. Lists are eligible to be used as indexes of other arrays.

Miles_per_gallon remains an array indexed by Car_type. Gallons_per_year remains defined as follows:

Gallons_per_year: Miles_per_year / Miles_per_gallon

The result of Gallons_per_year is now an array indexed by both Miles_per_year and Car_type (compare to the definitions in the section “Operation on a scalar and an array”):

Each value in the table is computed from the Miles_per_year for the column divided by the Miles_per_gallon for each Car_type (row). For example, 5000 miles per year divided by the large car’s 25 miles per gallon gives 200 gallons per year.

The list value for Miles_per_year propagates through the model as a new dimension to all its dependent variables. Recomputing the result for Operating_cost_per_year now gives a three-dimensional table with an added index of Miles_per_year:
The results for the other car_type can be displayed by clicking the diagonal arrow:

General rule for operations on arrays

We can summarize and generalize the behavior of an operation on two arrays with the following rule: An operation on two arrays yields an array whose indexes are the union of the indexes of the two arrays. In this way, Analytica combines arrays without requiring explicit iteration over each index. We call this feature of generalized operations for multidimensional values Intelligent Arrays.

**IF a THEN b ELSE c with arrays**

The IF a THEN b ELSE c construct (introduced in “IF a THEN b ELSE c” generalizes appropriately if any or all of a, b, and c are arrays. In other words, it fully supports Intelligent Arrays. For example, if condition a is an array of Booleans (true or false values), it returns an array with the same index, containing b or c as appropriate:

```
Variable X := -2..2
If X > 0 THEN 'Positive' ELSE IF X < 0 THEN 'Negative' ELSE 'Zero' →
```

```
<table>
<thead>
<tr>
<th></th>
<th>-2</th>
<th>-1</th>
<th>0</th>
<th>1</th>
<th>2</th>
</tr>
</thead>
<tbody>
<tr>
<td>'Negative'</td>
<td>'Negative'</td>
<td>'Zero'</td>
<td>'Positive'</td>
<td>'Positive'</td>
<td></td>
</tr>
</tbody>
</table>
```

If b and/or c are arrays with the same index(es) as a, it returns the corresponding the values from b or c according to whether a is true or false:

```
IF X >= 0 THEN Sqrt(X) ELSE 'Imaginary' →
```
Arrays and Indexes

Chapter 11

IF a THEN b ELSE c with arrays

The expression evaluates $\sqrt{x}$ for each value of $x$, even the negative ones, which return $\text{NAN}$, even though they are replaced by ‘Imaginary’ in the result.

To avoid evaluating all of b or c

Sometimes, you want to avoid evaluating elements of $b$ or $c$ corresponding to elements of $a$ that give errors or NULL results, to avoid wasting computation time on intermediate results that won’t be used in the final result, or because the computations will cause evaluation errors, not just warnings. In such cases, you can use explicit iteration, using a FOR or While loop over index(es) of $a$. See “Begin-End, ( ), and ‘;’ for grouping expressions”.

Omitting ELSE

If you omit the ELSE $c$ part, it usually gives a warning when it is first evaluated.

If you click Ignore Warnings, it returns NULL for elements for which $a$ is false:

$$\text{IF } x \geq 0 \text{ THEN } \sqrt{x} \rightarrow$$

After you have clicked Ignore Warnings, it will not give the warning again, even after you save and reopen the model.

Tip

Usually, you should omit the ELSE $c$ part of an IF construct only in a compound expression (see “Begin-End, ( ), and ‘;’ for grouping expressions”), when the IF $a$ THEN $b$ is not the last expression, but rather is followed by “;”. In this situation, the NULL result is not part of the result of the compound expression, and it gives no warning:

$$\text{BEGIN}$$
$$\hspace{1cm} \text{VAR } a := \text{Min}([x, y]);$$
$$\hspace{1cm} \text{IF } a<0 \text{ THEN } a:=0;$$
$$\hspace{1cm} \sqrt{a}$$
$$\text{END}$$

The dimensions of the result

If $a$ is an array containing some True and some False values, IF $a$ THEN $b$ ELSE $c$, evaluates both $b$ and $c$. The result contains the union of the indexes of all operands, $a$, $b$, and $c$. But, if $a$ is an atom or array whose value(s) are all true (1), it does not bother to evaluate $c$ and returns an array with the indexes of $a$ and $b$. Similarly, if all atoms in $a$
are false (0), it does not bother to evaluate b and returns an array with the indexes of a and c. This means that the values in the condition a can affect whether b and/or c are evaluated, and which indexes are included in the result.

IFALL a THEN b ELSE c  
If you don't want the dimensions of the result to vary with the value(s) in a, use the IFALL construct. This is like the IF construct, except that it always evaluates a, b, and c, and so the result always contains the union of the indexes of all of three operands.

IFALL requires the ELSE c clause. If omitted, it gives a syntax error.

IFONLY a THEN b ELSE c  
IFONLY has the advantage over IF (and IFONLY) that the dimensions of the result are always the same, no matter what the values of the condition a. The downside is that if a is an array and all its atoms are True (or all are False), it wastes computational effort calculating c (or b) even though its value is not needed for the result. IFALL also may waste memory (and therefore also time) by including the index(es) that are only in c (or b) even though the result has the same values over those indexes. The standard IF construct may also waste some memory when all of the values of array a are True (or all are False), because the result includes any index(es) of a that are not indexes of b (or c), even though the result must be the same over such index(es). In situations, where this is a concern, you may use a third conditional construct, IFONLY a THEN b ELSE c. Like IF, when all atoms of a are True (or all False), it evaluates only b (or only c). But, unlike IF, the result in these cases does include any index(es) of a that are not indexes of b (or c, respectively). Thus, IFONLY can be more memory-efficient.

In the vast majority of cases, you may just use IF without worrying about IFALL or IFONLY. The only reason to use IFALL is if you don't want the dimensions of results to vary with values of inputs. The only reason to use IFONLY is when memory is tight and it's common for condition a to be all true or all false.

To summarize the differences between these three constructs: If condition a is an atom or array containing only true (only False) values, IF and IFONLY evaluate only b (only c), whereas IFALL always evaluates both b and c. The result of IF contains the indexes of only b (only c). The result of IF contains the indexes of a and b (or c). The result of IFALL always contains the indexes of a, b, and c, and so its dimensions do not depend on the values of a.

If condition a is an array containing mixed true and false atoms, all three constructs behave identically: They evaluate a, b, and c, and the result contains the union of the indexes of a, b, and c.

IFALL requires the ELSE part. It is optional for IF and IFONLY, but recommended except when part of a compound expression, followed by ",".

Creating an index

An index is a class of variable used to identify a dimension of an array. The same index may identify the same dimension shared by many arrays. Sometimes, you may also use other classes of variables, such as a decision. Any variable defined as a list — one-dimensional array with no separate index — can serve as an index to an array. For clarity in your model, use an index variable whenever possible.

You create an index much like any other variable:

1. Select the edit tool and open a Diagram window.
2. Drag the parallelogram shape from the node palette to the diagram.
3. Type a title into the new index node.
4. You may define an index as a list (of numbers), list of labels, sequence, or other expression that generates a list. Here we define it as a list.

Create a list

To define a variable as a list, first select the variable and open one of the following:
- The variable’s Object window.
- The Attribute panel of the diagram (see “The Attribute panel” on page 23).
- In the Attribute panel, select Definition from the Attribute popup menu (see “Creating or editing a definition”) as the attribute to display.

To create a list:

1. Press the Expression popup menu above the definition field and select List (of numbers) or List of Labels (for text).

   ![List icon for the Expression popup menu]
   (If the variable already has a definition, Analytica confirms that you wish to replace it. Click OK to replace the definition with a one-element list.)

   A one-element list is displayed in the definition field.

2. Select the element by clicking it.
3. Type in a number or expression (for List) or text (for List of Labels).
4. Press Enter and type in the next value.
5. Repeat step 4 until you have entered all the values you want.
Creating an index

Autofill a list It gives the first cell of a list the default value of 1 (or the previous definition if it had one). When you press Enter or down-arrow, it adds a cell adding 1, or the increment between the two preceding cells, to the value of the preceding cell.

Create a list with the Sequence option For the classes of nodes that are often defined as lists, such as index and decision variables, the Expression popup menu includes the Sequence option.

The Sequence option provides a quick way to define a list of equally spaced numbers. When you select Sequence, the Object Finder opens, showing the Sequence() function.

After entering the Start, End, and Stepsize values, click OK; the definition field shows the Sequence button with its parameters.
Tip

To edit the sequence, click the **Sequence** button.

List vs. list of labels

You can display a list or list of labels in two ways: List view or Expression view. The List view displays by default; the **Expression** popup menu shows the list or list of labels icon.

The Expression view displays when you select the **Expression** icon in the **Expression** popup menu.

<table>
<thead>
<tr>
<th>List view</th>
<th>Expression view</th>
</tr>
</thead>
<tbody>
<tr>
<td><img src="image1" alt="List view" /></td>
<td>[1, 2, 3, 4, 5]</td>
</tr>
</tbody>
</table>

List (of numbers)

In a list of numbers (usually called simply a list), each value is a number or an expression that evaluates to a number. For example, the sequence of five integers above is a list.

List of labels

In a list of labels, every value is text. For example, the set of states below is a list of labels; in the Expression view, each label is contained in single quotation marks.

<table>
<thead>
<tr>
<th>List view</th>
<th>Expression view</th>
</tr>
</thead>
<tbody>
<tr>
<td><img src="image2" alt="List view" /></td>
<td>['Alabama', 'Alaska', 'Arizona', 'Arkansas']</td>
</tr>
</tbody>
</table>

To include a single quote (apostrophe) as part of the text in a label in Expression view, insert two adjacent single quotes, for example:

```plaintext
['can’t', 'won’t', 'didn’t']
```

Mixing numbers and text

A list can include a mix of cells containing text and numbers. In both views the text is contained in single quotation marks. For example:

<table>
<thead>
<tr>
<th>List view</th>
<th>Expression view</th>
</tr>
</thead>
<tbody>
<tr>
<td><img src="image3" alt="List view" /></td>
<td>[1, 'Alabama', 2, 'Alaska']</td>
</tr>
</tbody>
</table>

If you attempt to mix numbers and text in a list of labels, all the values will be treated as text. For example:
Editing a list

You can edit a list by changing, adding, or deleting cells (list items).

Insert a cell

To add a cell at the end of the list, select the last cell and press Enter or the down arrow key.

To insert a cell anywhere other than at the end of the list, select a cell and choose Insert Rows (Control+i) from the Edit menu. The value in the selected cell is duplicated in the new cell.

To insert several contiguous cells in the middle of the list, select the number of cells you want to insert and choose Insert Rows (Control+i) from the Edit menu. The value of the last selected cell is duplicated in the new cells.

Delete a cell

To delete one or more cells, select them and do one of the following:

- Choose Delete Rows (Control+k) from the Edit menu.
- Press Delete.

Tip

If you add or delete a cell in a list that is an index of an edit table, the corresponding elements of the table are also added or removed (see “Editing a table”).

Navigating a list

Use the up and down arrow keys to move the cursor up and down the list.

Functions that create indexes

Use the List option in the Expression popup menu to define a variable as a list of numbers or text values (labels) (see “Create a list”). You can also create a list within a variable definition using the constructs and functions described below.

\[
[ u_1, u_2, u_3, \ldots u_m ]
\]

A list of expressions, separated by commas and surrounded by square brackets, creates a list, whose values are \( u_1, u_2, u_3, \ldots u_m \).
Using square brackets to specify a list directly as an expression is equivalent to using the List or List of Labels options in the Expression popup menu, as described in "Create a list", according to the type of values, for example:

<table>
<thead>
<tr>
<th>Examples</th>
<th>[8000, 12K, 15K]</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>['VW', 'Honda', 'BMW']</td>
</tr>
</tbody>
</table>

**Tip**  If you draw an arrow from a node \( x \) into a variable \( y \) defined as list, it automatically adds \( x \) as the last element of the list. Or if \( x \) is already in the list it removes it. This is a handy way to make a list of variables.

\( m .. n \)

Returns an increasing sequence of integers from \( m \) to \( n \) if \( n \geq m \) or decreasing if \( n < m \). It is equivalent to \( \text{Sequence}(m, n) \). For example,

\[
\]

**Tip**  The parameters \( n \) and \( m \) must be atoms, that is single numbers. Otherwise, it would result in a non-rectangular array. See "Functions expecting atomic parameters" for information on using this construct in a way that supports array abstraction.

**Sequence** (\( \text{start, end, stepSize} \))

Creates a list of numbers increasing or decreasing from \( \text{start} \) to \( \text{end} \) by increments (or decrements) of \( \text{stepSize} \). \( \text{stepSize} \) is optional and must be a positive number; if it is omitted, Analytica uses increments of 1. \( \text{start, end, and stepSize} \) must be deterministic scalar numbers, not arrays.

Using this function is equivalent to using the Sequence option in the Expression popup menu, as described in “Create a list with the Sequence option”.

The expression \( m .. n \) using the operator \( ".." \) is a version of \( \text{Sequence}(m, n, 1) \), so it generates a list of sequential numbers from \( m \) to \( n \).

<table>
<thead>
<tr>
<th>Library</th>
<th>Array</th>
</tr>
</thead>
</table>

**Examples**

If \( \text{end} \) is greater than \( \text{start} \), the sequence is increasing:

\[
\text{Sequence}(1, 5) \rightarrow [1, 2, 3, 4, 5]
\]

If \( \text{start} \) is greater than \( \text{end} \), the sequence is decreasing:

\[
\text{Sequence}(5, 1) \rightarrow [5, 4, 3, 2, 1]
\]

If \( \text{start} \) and \( \text{end} \) are not integers, and if \( \text{stepSize} \) is not specified, it rounds them first:

\[
\text{Sequence}(1.2, 4.8) \rightarrow [1, 2, 3, 4, 5]
\]
If `stepSize` is specified, it can create non-integer values from `start` to `end` by `stepSize`:

\[ \text{Sequence}(0.5, 2.5, 0.5) \rightarrow [0.5, 1, 1.5, 2, 2.5] \]

### Subset (d)

Returns a list containing all the elements of `d`'s index for which `d`'s values are true (that is, non-zero). `d` must be a one-dimensional array.

**When to use** Use `Subset()` to create a new index that is a subset of an existing index.

**Library** Array

**Example**

\[ \text{Subset}(\text{Years} < 1987) \rightarrow [1985, 1986] \]

**Note:** See “Example data” for the definition of example variables.

### CopyIndex(i)

Makes a copy of the values of index `i`, to be assigned to a new index variable (global or local). For example, suppose you want to create a matrix of distances between a set of origins and destinations, where the destinations are the same set of cities as the origins:

- **Index Origins**

- **Index Destinations**
  - Definition: `CopyIndex(Origins)`

**Variable** `Flight_times := Table(Origins, Destinations)`

If `Destinations` was the same `Origins`, rather than a copy, the resulting table would have only one dimension. By defining `Destinations` with `CopyIndex()`, it becomes an independent dimension.

### Sortindex (d, i)

`d` is an array indexed by `i`. `SortIndex()` returns the elements of `i`, rearranged to indicate the ordering of the values in `d` (from smallest to largest value). The result is indexed by `i`. If `d` is indexed by dimensions other than `i`, each "column" is individually sorted, with the resulting sort order being indexed by the extra dimensions. To obtain the sorted array `d`, use the following:

\[ d[i=\text{Sortindex}(d,i)] \]

When `d` is a one-dimensional array, the second parameter is optional. When the second parameter is omitted, the result is an unindexed list. The one-parameter form should be used only when it is necessary to obtain an unindexed result, such as when the result is being assigned to an index variable. The one-parameter form cannot array abstract if a new dimension is added to `d`.

**Library** Array

**Examples**

\[ \text{Maint}\_\text{costs} \rightarrow \]
Chapter 11  Arrays and Indexes

Creating an array with an edit table

To define a variable as an edit table, you choose table from the expression menu above its definition:

1. Select the variable and open its definition by either:

```
LastName  FirstName  Company
1         Smith      Bob      Acme
2         Jones      John     Acme
3         Johnson    Bob      Floorworks
4         Smith      Bob      Acme
```

```
Unique(DataSet, PersonNum) \rightarrow [1, 2, 3]
Unique(DataSet[Field='Company'], PersonNum) \rightarrow [1, 3]
```
Creating an array with an edit table

1. The variable’s Object window.
2. The Attribute panel of the Diagram window (see “Creating or editing a definition”), and select Definition from the Attribute popup menu (see “Creating or editing a definition” on page 116), or

To create a table:

2. Press the Expression popup menu above the definition field and select Table:

If it already has a definition, click OK to confirms that you wish to replace it:

3. It opens the Indexes dialog so you can select the table’s indexes (dimensions). It will already list under Selected indexes any index variables from which you have drawn an arrow to this variable. You may keep them, remove them, or add more indexes:

4. Select a variable from the Indexes list and click the move button or double-click the variable, to select it as an index of the table. Repeat for each index you want.
4. Click OK to create the table and open the Edit Table window for editing the table’s values (see “Editing a table” on page 171).

Indexes dialog box

The Indexes dialog box contains these features (see figure above):

- **Preview**: A list of the values of the selected index variable. If the selected variable is not a list, it says “Can’t use as index.”
- **All Variables checkbox**: If checked, the Indexes list includes all variables in the model. If not checked, it lists only variables of the class Index and Decision, plus the variable being defined (Self) and Time. If you select this variable (Self) as an index, the variable itself holds the alternative index values.
- **Selected indexes**: A list of all indexes already selected for this variable.
- **New index**: Select to create a new index.

To create an index

You can create an index variable in the course of creating a table, in the following way:

1. Select new index from the variables list in the Indexes dialog box.
2. Enter a title for the index.
3. Click the Create button.
4. To make the new index an index of the table, click the button.

Enter the values of the Index in the Edit Table window (see the following section).

To remove an index from an array

1. Select the index from the Selected Indexes list.
2. Click the button.

Removing an index leaves the subarray for the first item in that index as the value of the entire array.

System index variables Run and Time

Analytica includes two system index variables: Run and Time. You can generally treat these index variables like any other index variable.

Run is the index for the array of sample values for probabilistic simulation. You can examine the array with the sample uncertainty mode (see “Sample”) or the Sample() function (see “Sample(x)”).

Time is the index for dynamic simulation. It is the only index permitted for cyclically dependent modeling (see “Dynamic Simulation”).
Editing a table

To open the Edit Table window, click the Edit Table button in either:

- The Object window (see “The Object window” on page 22)
- The Attribute panel of the diagram (see “The Attribute panel” on page 23)

In the Attribute panel, select Definition from the Attribute popup menu (see “Creating or editing a definition” on page 116).

The Edit Table window looks much like the Result window Table view (see “Viewing a result as a table” on page 30). The difference is that you can add indexes and edit the values in cells:

Edit a cell
Click the cell, and start typing to replace what’s in it. To add to what’s there, click three times to get a cursor in the cell, and type. You can use left-arrow and right-arrow keys to move the cursor. See “Shortcuts to navigate and edit a table” on page 174 for more. Press Enter to accept the value and to select the next cell, or click in another cell.

Tip
You may enter an expression into a table cell with operations, function calls, and so on. But, if the expression is complex, it’s easier to enter it as the definition of a new variable, and then just type the name of the variable into the table.

Select a cell
Click the cell once.

Select a range of cells
Drag cursor from a cell at one corner of a rectangular region to the cell at the opposite corner.

Copy and paste a cell or region
You can copy a cell or a range (two-dimensional rectangular region) of cells from a table or paste a cell into a region, just as with a spreadsheet:

1. Select the source cell or region as above, and choose Copy from the Edit menu or press Control+c.
2. Select the destination cell (or top-left cell of the destination region), and choose Paste from the Edit menu or press Control+v.

If you select a destination region that is n times larger (width, height, or both) than the source cell or region, it repeats the source n times in the destination.

Accept
Click ✔️ to accept all the changes you have made to the table. If you close a table, it will also accept the changes, unless you click ✗.

Cancel
Click ✗ to cancel all the changes you have made to the table since you opened it or last clicked ✔️.
Copy and paste to or from a spreadsheet

Copy and paste of a cell or region works much the same from a spreadsheet to an Analytica table or vice versa. If necessary, you can easily pivot the Analytica table so its rows and columns correspond with those in the spreadsheet. It copies numbers in exponential format with full precision, no matter what number format is used in the table, so that other applications can receive them with no problems.

Copy an entire table

To copy a table, including its row and column headers, click the top left cell to select the whole table. You can also copy a table with more than two dimensions: Select Copy table from the Edit menu. When you paste into a spreadsheet, it includes the name of the table, and all indexes, including the slicer index(es) for the third and higher dimensions.

Editing or extending indexes in an edit table

One convenient aspect of Intelligent Arrays is that you can edit and extend the indexes of an array right in the edit table, to change index values, insert or remove rows or columns, or, more generally, subarrays.

This works for an index defined as a list of numbers or list of labels. If an index is defined in another way — for example as \( m .. n \) or \( \text{Sequence}(x_1, x_2, dx) \) — you must edit the original index. Either way, all edit tables that use the changed index are automatically modified accordingly. ([#xref See “Splicing” for details.)

To edit or extend an index, either you must be in edit mode or the index variable you want to modify must have an input node. See “Creating an input node”.

Edit a cell in a row or column index

Click the cell once to select its row or column. Then double-click the cell to select its contents. Start typing to replace the text or number. Remember, the same change will happen to all tables that use that index.

Append a row

Click the bottom element of the row index to select the bottom row, and press the down-arrow key.

Append a column

Click the rightmost element of the column index to select the right column, and press the right-arrow key.

Insert a row or column

1. Click the row or column header to select the row or column before which you wish to insert a new one.
2. Select Insert Rows (or Insert Columns) from the Edit menu, or press or Control+i.

Normally, the new row or column contains zeros, but see [#xref Splicing] for more.

Delete a row or column

1. Click the row or column header to select the row or column you wish to delete.
2. Choose Delete Rows or Delete Columns from the Edit menu, or press Control+k.

Tip

When you try to change an index that is used by more than one edit table, it warns you that “Changing the size of this index will affect table definitions of other variables.” and gives the option of whether to continue.

Tip

If you intend your model to be used by end users with the Player or Power Player editions (that are fixed in browse mode) or intend to save your model as browse-only (if you have the Enterprise Edition), you can decide whether you want to allow your end users to be able to edit indexes as described above: Create an input node for each index that you want to let them change. Or don’t, if you want to prevent them changing an index.
Add an index  To add an index, use one of these two methods:

• Draw an arrow from the index to the node containing the table. When it asks if you want to add the index as a new dimension of the table, answer Yes.

• Click in the edit table to open the Indexes dialog (see “Indexes dialog box”). Double-click the index you want to add, and click OK.

When adding a new dimension to an edit table, it copies the values of the table to each new subarray over the new index. Thus, the expanded table has the same values for every element of the new index. This has no effect on other edit tables.

Remove an index  To remove an index, use one of these two methods:

• Draw an arrow from the index to the node containing the table. When it asks if you want to remove the index as a dimension of the table, answer Yes

• Click in the edit table to open the Indexes dialog (see “Indexes dialog box”). Double-click the index you want to remove, and click OK.

Tip  When removing a dimension from an edit table, it replaces the entire table by its subarray for the first value of the index you are removing. It deletes all the rest. Be careful, because you will lose all the data in the rest of the table! This has no effect on other edit tables.

Choice menus in an edit table

You can include a dropdown (pulldown) menu in any cell of an edit table to let end users select an option for each cell. Here is an example, in browse mode:

You use the Choice() function in the edit table cells, similar to using Choice to specify a single menu for a variable (see “Choice(i, n, inclAll)”):

1. Create a variable X as an edit table, in the usual way, selecting Table from the expr menu above its definition.

2. Create an Index variable, e.g., K, containing the list of options you want to make available from the menu(s), usually as a list of numbers or a list of labels.

3. In the edit table of X, in edit mode, enter Choice(K, 1, 0) into the first cell that you want to contain a menu. The second parameter 1 means that the first element of k is the default option. The third parameter 0 means that it does not show All as an option, normally what you want.
4. Copy and paste `choice(K, 1, 0)` from the first cell to any others you want also to contain the menu. You can also use other indexes than `K` if you want to include menus with other options. Here is an example viewed in edit mode, with dropdown menus in some but not all cells:

```
<table>
<thead>
<tr>
<th>Integrated subsystems</th>
<th>$1,500,000</th>
<th>Choice(Options, 0)</th>
<th>Choice(Options, 2, 0)</th>
<th>Choice(Options, 6, 0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Acronyms</td>
<td>$2,500,000</td>
<td>Choice(Options, 4)</td>
<td>Choice(Options, 4, 0)</td>
<td>Choice(Options, 5, 0)</td>
</tr>
<tr>
<td>Renewable dynamics</td>
<td>$3,200,000</td>
<td>Choice(Options, 5)</td>
<td>Choice(Options, 4, 0)</td>
<td>Choice(Options, 1, 0)</td>
</tr>
</tbody>
</table>
```

5. Select `X`, then select **Make Input** from the **Object** menu to make an input node for it. Move the input node to a good location.

**Tip** The variable containing the edit table with menus must have an input node — otherwise, you won’t be able to select from the menus or edit other cells in browse mode.

## Shortcuts to navigate and edit a table

These mouse operations and keyboard shortcuts let you navigate around a table, select a region, and search for text. They are the same as in Microsoft Excel, wherever this makes sense. `Control-PgUp` and `Control-PgDn` are exceptions.

The **current cell** is highlighted, or the first cell you selected in a highlighted rectangular region. In a region, the **anchor cell** is the corner opposite the current cell. If you select only one cell, the Anchor and Current are the same cell.

### Mouse operations

- **Mouse Click**: Click in a cell to make it the current cell.
- **Mouse Shift+Click**: Select the region from the previous anchor to this cell.
- **Mouse drag**: Select the region from the cell in which you depress the left mouse button to the cell in which you release the button.
- **Mouse wheel**: Scroll vertically without changing the selection.
- **Control+mouse wheel**: Scroll horizontally without changing the selection.

### Shortcuts to edit a table

These shortcut keys speed up editing a table. Inserting and deleting rows and columns works only if the index(es) are defined as an explicit list, not if it is computed or a sequence:

- **Downarrow**: If you have selected the last row, add a row.
- **Leftarrow**: If you have selected the right column, add a column.
- **Control-i**: If you have selected a row header, insert a row. If you have selected a column header, insert a column.
- **Control+k**: Delete a selected row or column.
### Search a table

**Control+f**  
Open the Find dialog to search for text in the table. It searches from the current cell and selects the first matching cell, if any.

**Control+g**  
Repeat the previous Find, starting in the next cell.

### Arrow keys

- **arrow (right, left, up, down)**  
  Move one cell in the given direction. At the end of row, right arrow wraps to the start of the next row. At the end of the last row, it wraps to top-left cell. Similarly, for the other keys.

- **Shift+arrow**  
  Move the current cell one cell in the given direction. The Anchor cell stays put, causing the selected region to grow or shrink. It does not wrap.

- **Control+arrow**  
  Move to the end of row or column in the given direction.

- **Shift+Control+arrow**  
  Move current cell to the end of row or column in the given direction, leaving the Anchor where it is, causing the selected region to grow (or flip).

- **End, arrow**  
  Two key sequence. Same as Control+arrow.

- **End, Shift+arrow**  
  Two key sequence. Same as Shift+Control+arrow.

### Home key

- **Home**  
  Move the anchor to the first column, and sets the current cell to be the anchor (so only one cell is selected). If you are in the row headers, moves the anchor and current to the first row.

- **Control+Home**  
  Select the top-left cell in the table. (Selects one cell.)

- **Control+End**  
  Select the bottom-right cell in the table. (Selects one cell.)

- **Shift+Control+Home**  
  Select the region between the anchor and the top left cell. (Leaves current as top left.)

### Page key

- **Page Up, Page Down**  
  Move the current cell up or down by the number of rows visible in the window, and scrolls up or down to show that cell. (Selects one cell.)

- **Control+Page Up, Control+Page Down**  
  Move the current cell left or right by the number of columns visible in the window, scrolling horizontally to show the new current cell. (This is not the same as Excel, in which Control+PgUp, Control+PgDown toggle between worksheets. Since we don’t have worksheets, these do something else useful.)

- **Shift+Page Up, Shift+Page Down**  
  Move the Current cell by the number of rows or columns that currently display on the screen, and scroll vertically by one page. Anchor stays the same, so that the currently selected region expands or shrinks by one page length.

- **Shift+Control+Page Up, Shift+Control+Page Down**  
  Same as Shift+Page Up, but horizontally rather than vertically.
Other keys

**Tab**  
Move one cell right. Same as right arrow.

**Shift+Tab**  
Move one cell left. Same as left arrow.

**Enter, Shift+Enter**  
If editing, accept change, selection remains on cell just edited. If not editing, but in edit mode, current cell becomes anchor cell and begin editing that cell.

**Return**  
If editing, accept changes. Move anchor down one cell, wrapping to top of next column if anchor is at the bottom. Set current cell to anchor (so only one cell is selected). If not editing, just move, do not start editing.

**Shift+Return**  
If editing, accept changes. Move anchor cell up one cell, wrapping to bottom of previous column if at top. Set current to anchor, so only one cell is selected.

**Control+a**  
Select all (body) cells. If a row/col header is selected, selects all rows/cols.
Analytica provides a large collection of built-in functions for performing common mathematical, financial, statistical, and array computations.

This chapter explains the nature and benefits of Intelligent Arrays™, and describes a variety of more advanced array functions that enable you to make the best use of them, including functions for reducing, transforming, selecting, flattening, interpolating arrays; matrix functions and financial functions.

Functions for uncertainty and sensitivity analysis are covered in later chapters.
This chapter describes Analytica’s advanced built-in functions for dealing with arrays. It is organized by the type of function:

- Functions that create arrays (“Functions that create arrays”).
- Functions that reduce an array to another array with one fewer dimension (“Array-reducing functions”).
- Functions that return an array with the same number of dimensions as the input array (“Transforming functions”).
- Functions that select part or a slice of an array (“Selecting, slicing, and subscripting arrays”).
- Functions that interpolate values between array elements (“Interpolation functions”).
- Other array functions (“Other array functions”).
- Matrix functions for two-dimensional arrays (“Matrix functions”).
- Functions commonly used for financial computations (“Financial functions”).

**Intelligent Arrays™**

Intelligent Arrays™ are one of the most useful and powerful features of Analytica, yet their full implications are easy to miss. Consider this definition in Analytica:

\[
\text{Variable Profit := Revenues - Expenses}
\]

It works equally well if Profits, Revenues, and Expenses are each scalars (single numbers), or arrays of one or more dimensions. If Revenues and Expenses are both indexed by Year, it computes the Profits for each Year, using the corresponding Revenues and Expenses for that Year, as in this example:
The figure below shows an influence diagram above and corresponding array values below.

![Influence Diagram](image1)

The definition of Profit remains the same, no matter what the dimensions of Revenues and Profits. If Revenues is a scalar (a single number), Profit treats it as if it is the same each Year.

Or if Revenues are specified for three different Scenarios — Low, Medium, and High — it computes the corresponding Profit for each Scenario, whether or not Expenses vary by Scenario.

![Influence Diagram](image2)

Now Revenues is indexed by Scenario as well as Year:

![Influence Diagram](image3)

**The value of flexibility** This flexibility is very convenient for the modeler. Changing dimensions is much more complicated in a spreadsheet or standard programming language. In a spreadsheet, you would have to explicitly create each of the three variables as a table with the required number of dimensions. And you would have to craft carefully the formula with
the requisite relative cell references, and copy it into each cell of Profit. In a programming language, such as Fortran, C++, Java, or Visual Basic, you would have to put the formula inside loops to iterate over the dimensions. A simple one-dimensional case might look something like this:

```
For Years := 2000 To 2010 DO
    Profit[Years]:=Revenues[Years] - Expenses[Years]
```

If you decide to add a dimension, such as Scenario to Revenues and Profit, you would need to redimension both variables, add another For loop over Scenario, and add a second subscript to Profit and Revenues, nearly doubling the complexity of the program.

To do the same thing in a spreadsheet would require adding two extra rows to the tables of Revenues and Profit, copying the name Scenario and its three values, Low, Medium, and High as row headers into both tables, rewriting the base cell formula in Profit, and finally stretching the cell formula across the columns and then down the two new rows. The effort to create the two-dimensional model is more than double the effort to create original one-dimensional model, which is itself more than double the scalar model.

Now consider extending the time horizon from 2007 to 2010, a common need in business models. In Analytica, you simply edit the definition of Year, changing the 2007 to 2010. The arrays for all three variables extend automatically over the three extra years. The input edit tables for Revenues and Expenses are filled out with zeroes for these new years. You just need to open up those tables and fill in the numbers you want. In a spreadsheet, you would need to extend each table by hand, including copying the Year column headers 2008, 2009, and 2010 for each table, and stretching the formulas for Revenue over nine new cells.

### Array abstraction and Intelligent Arrays

All this work to expand the tables and the formulas for Revenue is distracting and quite unnecessary — the relationship between Profit, Revenues and Expenses should be entirely separate from whatever dimensions they happen to have. The principle of abstracting the representation of the relationships between the variables from the dimensions of those variables is sometimes known as array abstraction. Few computer languages offer support for array abstraction. Analytica offers a unique and extensive approach to array abstraction, which is the basis of its Intelligent Arrays. Once you have mastered the basics of Intelligent Arrays, you may find it hard to imagine going back to a modeling environment (such as a spreadsheet or standard programming language) without array abstraction.

### Choosing the right level of detail

Intelligent Arrays provides a flexibility that greatly simplifies the process of developing a model. When starting a model, it is rarely obvious how large and how detailed to make each dimension. Should time be modeled as years, quarters, or months? Should the time horizon be 5 years, 10 years, or 20 years? Is it necessary to treat each geographic region separately, and if so, by continent, nation, or state (province)? How you answer these questions has a large effect not only the accuracy of the model, but also on the quantity of data you will need, the effort to build and verify the model, and the computer resources (time and memory) needed to calculate them.

Ideally, you specify the essential relationships between the variables first, and decide their dimensions later. You may want to try different levels of detail, starting out with few and simple dimensions, then refining the model by expanding or adding dimensions. You should be able to experiment with the level of detail and computational effort until you get a good balance between effort and precision. With spreadsheets and conven-
Errors, testing, and reliability

Array abstraction also promotes reliability by reducing errors and making any errors easier to detect. In a spreadsheet, there are several easy ways to make errors when copying cell references, resulting in frequent bugs that are hard to detect. For example, mistakes in absolute versus relative cell references, or accidentally stretching a sum over only part rather than all of a row or column. In programming languages, it is also easy to make errors in handling dimensions, such as confusing rows and columns in the sequence of subscripts. With Analytica, the relationships are much simpler. There is a single expression defining each variable, rather than one for each cell in the result. Expressions are uncluttered by looping constructs. You define a Sum over an identified Index, no matter what other dimensions an array may have. This simplicity makes expressions easier to write in the beginning and easier to review for correctness later. Furthermore, provided the formulas support array abstraction, there is no need to modify formulas as you extend or add dimensions — in those variables, or elsewhere in the model. You can have justifiable confidence that the model remains correct as you extend or add dimensions.

Intelligent Arrays enable several other important capabilities of Analytica. One key feature is support for representing and propagating uncertainty. An uncertain variable is represented as a random sample of values from its underlying probability distribution, over a dimension indexed by Run. The Run index has values from 1 to the sample size. Each expression containing one or more uncertain variables automatically computes its result over all the random samples, generating a result indexed by Run (as well as any other dimensions). Array abstraction means that this works, without you (the modeler) having to worry about this extra dimension. Similarly, in parametric analysis, you can set one (or more) input variables (parameters) each to a number of alternative values to explore the effects of this variation. These values create an array indexed by the input parameters, which is automatically propagated through the model to generate a corresponding table of values for each output, indexed by the alternative values of its parametric inputs.

Exceptions to array abstraction

The vast majority of Analytica functions and constructs fully support Intelligent Arrays — that is, they automatically generalize from atomic values to multidimensional array — but a few do not. When you use these latter, you need to take special care to ensure that your models will array abstract conveniently when you add or modify dimensions. See “Ensuring array abstraction” on page 359 for details.

Functions that create arrays

Use the Table option in the Expression popup menu to define a variable as an array (see “Creating an array with an edit table”).

For more flexibility and control, you can define a variable as an array by entering the Array() or Table() function as an expression.
Functions that create arrays

Array(i1, i2, … in, a)

Assigns a set of indexes, i1, i2, … in, as the indexes of the array a, with i1 as the index of the outermost dimension (changing least rapidly), i2 as the second outermost, and so on. a must have at least n dimensions. The elements of a are listed in square brackets as the last parameter, or a is a previously defined array.

Use Array() to specify an array directly as an expression. Array() is similar to Table(); in addition, it lets you define an array with repeated values (see Example 3), and change indexes of a previously defined array (see Example 4).

Example 1

Definition viewed as an expression:

```
Array(Car_type, [32, 34, 18])
```

Definition viewed as a table:

```
<table>
<thead>
<tr>
<th>Car_type</th>
<th>VW</th>
<th>Honda</th>
<th>BMW</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>32</td>
<td>34</td>
<td>18</td>
</tr>
</tbody>
</table>
```
Chapter 12: More Array Functions

Functions that create arrays

Note: Example variables are defined in “Creating an array with an edit table”.

**Example 2**
If an array has multiple dimensions, then the elements are listed in nested brackets, following the structure of the array as an array of arrays (of arrays..., and so on, according to the number of dimensions).

Definition viewed as an expression:

Array(Car_type, Years, [[8K, 9K, 9.5K, 10K], [12K, 13K, 14K, 14.5K], [18K, 20K, 21K, 22K]])

Definition viewed as a table:

<table>
<thead>
<tr>
<th>Car_type</th>
<th>Years</th>
</tr>
</thead>
<tbody>
<tr>
<td>VW</td>
<td>8000</td>
</tr>
<tr>
<td>Honda</td>
<td>12K</td>
</tr>
<tr>
<td>BMW</td>
<td>18K</td>
</tr>
</tbody>
</table>

The size of each array in square brackets must match the size of the corresponding index. In this case, there is an array of three elements (for the three car types), and each element is an array of four elements (for the four years). An error message displays if these sizes don’t match. See also “Size(u)”.

**Example 3**
If an element is a scalar where an array is expected, Array() expands it to create an array with the scalar value repeated across a dimension.

Definition viewed as an expression:

Array(Car_type, Years, [[8K, 9K, 9.5K, 10K], 13K, [18K, 20K, 21K, 22K]])

Definition viewed as a table:

<table>
<thead>
<tr>
<th>Car_type</th>
<th>Years</th>
</tr>
</thead>
<tbody>
<tr>
<td>VW</td>
<td>8000</td>
</tr>
<tr>
<td>Honda</td>
<td>13K</td>
</tr>
<tr>
<td>BMW</td>
<td>18K</td>
</tr>
</tbody>
</table>

**Example 4**
Use Array() to change an index of a previously defined array.

Car_model:

Table_a: Table(Car_type) (32, 34, 18)

Table_b: Array(Car_model, Table_a) → Car_model

<table>
<thead>
<tr>
<th>Car_model</th>
</tr>
</thead>
<tbody>
<tr>
<td>Jetta</td>
</tr>
<tr>
<td>Accord</td>
</tr>
<tr>
<td>32</td>
</tr>
</tbody>
</table>

Table (i1, i2, … in) (u1, u2, u3, … um)

Creates an n-dimensional array of m elements, indexed by the indexes i1, i2, … in. In the set of indexes, i1 is the index of the outermost dimension, varying the least rapidly.
The second set of parameters, \( u_1, u_2 \ldots u_m \), specifies the values in the array. The number of values, \( m \), must equal the product of the sizes of all of the dimensions.

Each \( u \) is an expression that evaluates to a number, text value or probability distribution. It can also evaluate to an array, causing the dimensions of the entire table to increase. \( u \) cannot be a literal list.

Both sets of parameters are enclosed in parentheses; the separating commas are optional except if the table values are negative.

Use \( \text{Table}() \) to specify an array directly as an expression. \( \text{Table}() \) is similar to \( \text{Array}() \); \( \text{Table}() \) requires \( m \) numeric or text values.

A definition created as a table from the \textit{Expressions} popup menu uses \( \text{Table}() \) in expression view.

**Library**

Array

**Example 1**

Definition viewed as an expression:

\[
\text{Table}(\text{Car\_type}) (32, 34, 18)
\]

Definition viewed as a table:

```
Car\_type ▼
<table>
<thead>
<tr>
<th>VW</th>
<th>Honda</th>
<th>BMW</th>
</tr>
</thead>
<tbody>
<tr>
<td>32</td>
<td>34</td>
<td>18</td>
</tr>
</tbody>
</table>
```

**Example 2**

Definition viewed as an expression:

\[
\text{Table}(\text{Car\_type, Years})
\]

\( (8K, 9K, 9.5K, 10K, 12K, 13K, 14K, 14.5K, 18K, 20K, 21K, 22K) \)

Definition viewed as a table:

```
Car\_type ▼, Years ▼
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>VW</td>
<td>8000</td>
<td>9000</td>
<td>9500</td>
</tr>
<tr>
<td>Honda</td>
<td>12K</td>
<td>13K</td>
<td>14K</td>
</tr>
<tr>
<td>BMW</td>
<td>18K</td>
<td>20K</td>
<td>21K</td>
</tr>
</tbody>
</table>
```

**Example 3**

A table created with blank (zero) cells appears in expression view without the second set of parameters.

Definition viewed as a table:

```
Car\_type ▼, Years ▼
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>VW</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>Honda</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>BMW</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
</tbody>
</table>
```

Definition viewed as an expression:

\[
\text{Table}(\text{Car\_type, Years})
\]
Array-reducing functions

An array-reducing function operates across a dimension of an array and returns a result that has one dimension less than the number of dimensions of its input array. When applied to an array of \(n\) dimensions, a reducing function produces an array that contains \(n-1\) dimensions.

The function \(\text{Sum}(x, i)\) illustrates some properties of reducing functions.

**Examples**

\[
\text{Sum(Car_prices, Car_type)} \rightarrow
\]

<table>
<thead>
<tr>
<th>Years</th>
<th>1985</th>
<th>1986</th>
<th>1987</th>
<th>1988</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>38K</td>
<td>42K</td>
<td>44.5K</td>
<td>46.5K</td>
</tr>
</tbody>
</table>

\[
\text{Sum(Car_prices, Years)} \rightarrow
\]

<table>
<thead>
<tr>
<th>Car_type</th>
<th>VW</th>
<th>Honda</th>
<th>BMW</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>36.5K</td>
<td>53.5K</td>
<td>81K</td>
</tr>
</tbody>
</table>

\[
\text{Sum(Sum(Car_prices, Years), Car_type)} \rightarrow 171K
\]

**Tip**

The second parameter, \(i\), specifying the dimension over which to sum, is optional. But if the array, \(x\), has more than one dimension, Analytica may not sum over the dimension you expect. For this reason, it is safer always to specify the dimension index explicitly in \(\text{Sum}()\) or any other array-reducing function.

If the index, \(i\), is not a dimension of \(x\), \(\text{Sum}(x, i)\) returns \(x\) unreduced, but multiplied by the size (number of elements) of \(i\). The reason is that if \(x\) is not indexed by \(i\), it means that it has the same value for all values of \(i\). This is true even if \(x\) is an atom with no dimensions:

\[
\text{Variable } x := 5
\]

\[
\text{Sum}(x, \text{Car_type}) \rightarrow 15
\]

because \(\text{car_type}\) has three elements. In this way, if we later decide to change the value for \(x\) for each value of \(i\), we can redefine \(x\) as an edit table indexed by \(i\). Any expression containing a sum or other reducing function on \(x\) will work correctly as the number of dimensions changes.

**Sum(x, i)**

Returns the sum of array \(x\) over the dimension indexed by variable \(i\).

**Library**

Array

**Examples**

\[
\text{Sum(Mpg)} \rightarrow 91
\]

\[
\text{Sum(Car_prices, Years)} \rightarrow
\]

<table>
<thead>
<tr>
<th>Car_type</th>
<th>VW</th>
<th>Honda</th>
<th>BMW</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>36.5K</td>
<td>53.5K</td>
<td>81K</td>
</tr>
</tbody>
</table>
Product(x, i)

Returns the product of all of the elements of x, along the dimension indexed by i.

Library
Array

Examples
Product(Mpg) → 27.3K
Product(Cost, Mpg) →
Car_type ▶

<table>
<thead>
<tr>
<th>VW</th>
<th>Honda</th>
<th>BMW</th>
</tr>
</thead>
<tbody>
<tr>
<td>5.905G</td>
<td>14.47G</td>
<td>28.78G</td>
</tr>
</tbody>
</table>

Average(x, i)

Returns the mean value of all of the elements of array x, averaged over index i.

Library
Array

Examples
Average(Mpg) → 30.33
Average(Car_prices, Car_type) →
Years ▶

<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>12.67K</td>
<td>14K</td>
<td>14.83K</td>
<td>15.5K</td>
</tr>
</tbody>
</table>

Max(x, i)

Returns the highest valued element of x along index i.

Library
Array

Examples
Max(Years) → 1988
Max(Car_prices, Years) →
Car_type ▶

<table>
<thead>
<tr>
<th>VW</th>
<th>Honda</th>
<th>BMW</th>
</tr>
</thead>
<tbody>
<tr>
<td>10K</td>
<td>14.5K</td>
<td>22K</td>
</tr>
</tbody>
</table>

To obtain the maximum of two numbers, first turn them into an array:

Max([10, 5]) → 10

Min(x, i)

Returns the lowest valued element of x along index i.

Library
Array

Examples
Min(Years) → 1985
Min(Car_prices, Years) →
Car_type ▶

<table>
<thead>
<tr>
<th>VW</th>
<th>Honda</th>
<th>BMW</th>
</tr>
</thead>
<tbody>
<tr>
<td>8000</td>
<td>12K</td>
<td>18K</td>
</tr>
</tbody>
</table>
To obtain the minimum of two numbers, first turn them into an array:

Min([10, 5]) → 5

**Argmax(a, i)**

Returns the item of index i for which array a is the maximum. If a has more than one value equal to the maximum, it returns the index of the last one.

**Library** Array

**Example**

Argmax(Car_prices, Car_type) → Years

<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>BMW</td>
<td>BMW</td>
<td>BMW</td>
<td>BMW</td>
<td></td>
</tr>
</tbody>
</table>

**Argmin(a, i)**

Returns the corresponding value in index i for which array a is the minimum. If more than one value equals the minimum, returns the index of the last occurrence.

**Library** Array

**Example**

Argmin(Car_prices, Car_type) → Years

<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>VW</td>
<td>VW</td>
<td>VW</td>
<td>VW</td>
<td></td>
</tr>
</tbody>
</table>

**CondMin( X : Array[I], cond : Boolean[I] ; i : IndexType )**

**CondMax( X : Array[I], cond : Boolean[I] ; i : IndexType )**

Conditional Min and Max. CondMin() returns the smallest, and CondMax() returns the largest values along a given index, i, that satisfies condition cond.

**Tip** These functions do not support named parameter syntax.

**Library** Array

**Syntax**

CondMin( X : Array[i], cond : Boolean[i] ; i : IndexType )
CondMax( X : Array[i], cond : Boolean[i] ; i : IndexType )

**Subindex(a, u, i)**

Returns the value of i corresponding to value u in array a. If more than one value corresponds, returns the index value of the last occurrence. For the values that do not correspond, returns undefined (shows as blank; see also “Isundef(x)”).

Argmax() uses Subindex(a, Max(a, i), i) to return the index value corresponding to the maximum value in a. See “Transforming functions”.

**Library** Special
Examples

Subindex(Car_prices, 12K, Car_type) →
Years

<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Honda</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Subindex(Car_prices, 12K, Years) →
Car_type

<table>
<thead>
<tr>
<th>VW</th>
<th>Honda</th>
<th>BMW</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>1985</td>
<td></td>
</tr>
</tbody>
</table>

If u is an array of values, an array of index values is returned.

Subindex(Car_prices, [12K, 21K], Car_type) →
Subindex ▼, Years

<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>12K</td>
<td>Honda</td>
<td></td>
<td></td>
</tr>
<tr>
<td>21K</td>
<td></td>
<td>BMW</td>
<td></td>
</tr>
</tbody>
</table>

PositionInIndex(a, x, i)

Returns the position in index i — that is, a number from 1 to the size of index i — of the last element of array a equal to x; if no element is equal, it returns 0.

When array a is multidimensional, the result will be reduced by one dimension, dimension i.

Library Array

Examples

When the array is one-dimensional.

Index I := ['A', 'B', 'C']
Variable A := Array(I, [1, 2, 2])
PositionInIndex(A, 1, I) → 1
PositionInIndex(A, 2, I) → 3
PositionInIndex(A, 5, I) → 0

Tip

PositionInIndex() is the positional equivalent of SubIndex(). It is useful when i contains duplicate values, in which case SubIndex() is insufficient.

More examples and tips

When the array is multidimensional:

PositionInIndex(Car_prices, 14K, Car_type) →
Years

<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>0</td>
<td>0</td>
<td>2</td>
</tr>
</tbody>
</table>

Tip

Parameter a is optional. When omitted, it returns the position of x in the index i, or 0 if not found. The syntax @i=x (see returns the same result as PositionInIndex(x,i):

PositionInIndex('B',I) → @I = 'B' → 2
PositionInIndex('D',I) → @I = 'D' → 0

When the array parameter is omitted:
PositionInIndex(, 'Honda', Car_type) \rightarrow 2
PositionInIndex(, 'VW', Car_type) \rightarrow 1

@: Index Position Operator

The position of value \( x \) in an index \( i \) is the integer \( n \) where \( x \) is the \( n^{th} \) element of \( i \). \( n \) is a number between 1 and \( \text{Size}(i) \). The first element of \( i \) is at position 1; the last element of \( i \) is at position \( \text{Size}(i) \). The position operator @ offers three ways to work with positions:

- \( @i \rightarrow \) an array of integers from 1 to \( \text{Size}(i) \) indexed by \( i \).
- \( @[i=x] \rightarrow \) the position of value \( x \) in index \( i \), or 0 if \( x \) is not an element of \( i \).
- \( e[@i=n] \rightarrow \) the \( n^{th} \) slice of the value of expression \( e \) over index \( i \).

Examples

Car_type:

\[
\begin{array}{c|c|c}
\text{VW} & \text{Honda} & \text{BMW} \\
\hline
1 & 2 & 3 \\
\end{array}
\]

\( @\text{Car_type} \rightarrow 2 \)
\( \text{Car_type}@\text{Car_type} = 2 \rightarrow \text{Honda} \)

More examples and tips

Assume \( \text{Time} : \) and \( \text{Years} := \text{Time} + 2007 : \)

\[
\begin{array}{c|c|c|c|c|c}
\text{Year} & 2007 & 2008 & 2009 & 2010 & 2011 \\
\hline
\text{Time} & 0 & 1 & 2 & 3 & 4 \\
\hline
\end{array}
\]

\( @\text{Time} \rightarrow \)
\( \text{Time} \rightarrow \)

\[
\begin{array}{c|c|c|c|c|c}
\text{Year} & 2007 & 2008 & 2009 & 2010 & 2011 \\
\hline
\text{Time} @\text{Time} = 2 \rightarrow 3 \\
\text{Time} @\text{Time} = 3 \rightarrow \)
\( \text{Time} \rightarrow \)

\[
\begin{array}{c|c|c|c|c|c}
\text{Year} & 2007 & 2008 & 2009 & 2010 & 2011 \\
\hline
\text{Time} @\text{Time} = 3 \rightarrow 2 \\
\text{(Time} + 2007) @\text{Time} = 3 \rightarrow 2009 \\
\text{Years} @\text{Time} = 3 \rightarrow 2009 \\
\end{array}
\]

Tip

You can use the slice variation to re-index an array by another array having the same length but different elements. For example, Suppose \( \text{Revenue} \) is indexed by \( \text{Time} \), then
the following expression returns the same array indexed by \textit{Years}:
\[
\text{Revenue[@Time=@Years]}
\]

For additional information consult the Analytica wiki:

\textbf{Area}(r, l, x1, x2)

Returns the area (sum of trapezoids) under array \( r \) across index \( l \) between \( x1 \) and \( x2 \). \( l \) must contain increasing numbers. \( x1 \) and \( x2 \) are optional; if they are not specified, the area is calculated across all of \( l \).

If \( x1 \) or \( x2 \) fall outside the range of values in \( l \), the first value (for \( x1 \)) or last value (for \( x1 \)) are used. \texttt{Area()} computes the total integral across \( l \), returning a value with one less dimension than \( r \). Compare \texttt{Area()} to \texttt{Integrate()} (see “Integrate(r, i)”).

\begin{tabular}{|l|l|l|l|}
\hline
Car_type & Mpg \\
\hline
VW & 9653 & 12.42K & 15.18K \\
Honda & 10.11K & 12.84K & 15.86K \\
BMW & 13.65K & 16.42K & 19.18K \\
\hline
\end{tabular}

\textbf{Transforming functions}

A \textit{transforming function} operates across a dimension of an array and returns a result that has the same dimensions as its input array.

The function \texttt{Cumulate(x, l)} illustrates some properties of transforming functions.

\begin{tabular}{|l|l|l|l|l|}
\hline
\text{1985} & \text{1986} & \text{1987} & \text{1988} \\
\hline
VW & 8000 & 17K & 26.5K & 36.5K \\
Honda & 12K & 25K & 39K & 53.5K \\
BMW & 18K & 38K & 59K & 81K \\
\hline
\end{tabular}

The second parameter, \( l \), specifying the dimension over which to cumulate, is optional. But if the array, \( x \), has more than one dimension, Analytica may not cumulate over the dimension you expect. For this reason, it is safer \textit{always} to specify the dimension index explicitly in any transforming function.

\textbf{Cumulate(x, l)}

Returns an array with each element being the sum of all of the elements of \( x \) along dimension \( l \) up to, and including, the corresponding element of \( x \).
If \( x \) is not indexed by \( i \), \( \text{Cumulate}(x, I) \) operates as if \( x \) were indexed by \( i \), but constant across \( i \). Using this, a convenient trick for numbering the elements of an index is to use \( \text{Cumulate}(1, i) \).

Library Array

Example

\[
\text{Cumulate(Cost\_in\_time, Time)} \rightarrow \\
\text{Mpg \ , Time \ , Car\_type = VW} 
\]

\[
\begin{array}{cccccc}
0 & 1 & 2 & 3 & 4 \\
26 & 2185 & 4479 & 6888 & 9417 & 12.07K \\
30 & 2810 & 5761 & 8859 & 12.11K & 15.53K \\
35 & 3435 & 7042 & 10.83K & 14.8K & 18.98K \\
\end{array}
\]

\[
\text{Cumulate(1,Car\_type)} \rightarrow \\
\text{Years} \\
\]

<table>
<thead>
<tr>
<th>VW</th>
<th>Honda</th>
<th>BMW</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>2</td>
<td>3</td>
</tr>
</tbody>
</table>

Uncumulate (\( x, i, \) firstElement)

\( \text{Uncumulate}(x, i) \) returns an array whose first element (along \( i \)) is the first element of \( x \), and each other element is the difference between the corresponding element of \( x \) and the previous element of \( x \). \( \text{Uncumulate}(x, i, \) firstElement\( ) \) returns an array with the first element along \( i \) equal to \( \) firstElement\( \) and each other element equal to the difference between the corresponding element of \( x \) and the previous element of \( x \).

\( \text{Uncumulate}(x, i) \) is the inverse of \( \text{Cumulate}(x, i) \). \( \text{Uncumulate}(x, i, 0) \) is similar to a discrete differential operator.

Library Array

Example

\[
\text{Uncumulate(Cost\_in\_time, Time)} \rightarrow \\
\text{Mpg \ , Time \ , Car\_type = VW} 
\]

\[
\begin{array}{cccccc}
0 & 1 & 2 & 3 & 4 \\
26 & 2185 & 109 & 115 & 120 & 127 \\
30 & 2810 & 141 & 147 & 155 & 163 \\
35 & 3435 & 172 & 180 & 189 & 199 \\
\end{array}
\]

\[
\text{Uncumulate(Cost\_in\_time, Time,0)} \rightarrow \\
\text{Mpg \ , Time \ , Car\_type = VW} 
\]

\[
\begin{array}{cccccc}
0 & 1 & 2 & 3 & 4 \\
26 & 0 & 109 & 115 & 120 & 127 \\
30 & 0 & 141 & 147 & 155 & 163 \\
35 & 0 & 172 & 180 & 189 & 199 \\
\end{array}
\]

Cumproduct(x, i)

Returns an array with each element being the product of all of the elements of \( x \) along dimension \( i \) up to, and including, the corresponding element of \( x \).

Library Array
Example
Cumproduct(Cost_in_time, Time) →
Mpg ▼, Time ▶, Car_type = VW

<p>| | | | | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>26</td>
<td>2185</td>
<td>5.012M</td>
<td>12.07G</td>
<td>30.54T</td>
</tr>
<tr>
<td>30</td>
<td>2810</td>
<td>8.292M</td>
<td>25.69G</td>
<td>83.57T</td>
</tr>
<tr>
<td>35</td>
<td>3435</td>
<td>12.39M</td>
<td>46.92G</td>
<td>186.6T</td>
</tr>
</tbody>
</table>

Rank(x, i)

Returns an array of the rank values of x across index i. The lowest value in x has a rank value of 1, the next-lowest has a rank value of 2, and so on. i is optional if x is one-dimensional. If i is omitted when x is more than one-dimensional, the innermost dimension is ranked.

If two values are equal, they receive the same rank and the next higher value receives a rank 2 higher.

Library Array

Examples
Rank(Mpg) →
Mpg ▼

<p>| | | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>26</td>
<td>30</td>
<td>35</td>
</tr>
<tr>
<td>1</td>
<td>2</td>
<td>3</td>
</tr>
</tbody>
</table>

Rank(Car_prices, Car_type) →
Car_type ▼, Years ▶

<p>| | | | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>VW</td>
<td>1</td>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>Honda</td>
<td>2</td>
<td>2</td>
<td>2</td>
</tr>
<tr>
<td>BMW</td>
<td>3</td>
<td>3</td>
<td>3</td>
</tr>
</tbody>
</table>

Integrate(r, i)

Returns the result of applying the trapezoidal rule of integration of array r over index i. Integrate() computes the cumulative integral across i, returning a value with the same number of dimensions as r. Compare Integrate() to Area() (see page 186).

An alternative syntax is Integrate(R1, R2, I), which returns the integral of array R1 over array R2. If R2 has one dimension, its index must also be an index of R1 and I is optional. If R2 has more than one dimension, then I is required and must be an index of both R1 and R2.

Library Array

Example Integrate(Cost_in_time, Time) →
Mpg ▼, Time ▶, Car_type = VW

<p>| | | | | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>26</td>
<td>0</td>
<td>2240</td>
<td>4591</td>
<td>7060</td>
</tr>
<tr>
<td>30</td>
<td>0</td>
<td>2881</td>
<td>5905</td>
<td>9081</td>
</tr>
<tr>
<td>35</td>
<td>0</td>
<td>3521</td>
<td>7218</td>
<td>11.1K</td>
</tr>
</tbody>
</table>
Normalize(r, i)

Returns an array that is normalized array r, so the area across index i is 1.

Normalize() does not force the values along index i to sum to 1; to make the values sum to 1, divide r by Sum(r, i).

An alternative syntax is Normalize(r1, r2, i), which returns the normalized array of array r1 over array r2. If r2 has one dimension, its index must also be an index of r1 and i need not be stated. If r2 has more than one dimension, then i is required and must be an index of r1 and r2.

Library | Array
Example | Normalize(Cost_in_Time, Time) → Mpg, Time, Car_type = VW

<table>

</tbody>
</table>

Selecting, slicing, and subscripting arrays

These constructs and functions select a slice or subarray of an array. The result may be a single cell, or a subarray, with (usually) one less dimension than the array from which it was sliced.

X[I=V]: Subscript construct

The most commonly used method to extract a subarray is the subscript construct:

\[ X[\text{I = V}] \]

This returns the subarray of \( X \) for which index I has value V. If V is not a value of index I, it returns NULL, and usually gives a warning.

If \( X \) does not have I as an index, it just returns \( X \). The rationale is that array \( X \) gives the value of \( X \) for each combination of indexes that it is indexed by. If it is not indexed by I, that means \( X \) has the same value for all values of I.

You can apply the subscript construct to an expression:

\[(\text{Revenue} - \text{Cost})[\text{Time} = 2010]\]

Indexing by name not position

You may subscript over multiple dimensions, for example:

\[ X[\text{I=V, J=U}] \]

You get the same result from:

\[ X[\text{J=U, I=V}] \]

You can specify the indexes in any sequence. Unlike most computer languages, with Analytica you identify the dimension you want to subscript over by naming each index — so you don’t need to remember which index refers to rows, to columns, or higher dimensions. Rows and columns are not intrinsic to the array representation — they are they are just a matter of how you choose to display the array in a table.
The value V can be an array with some index other than I of values from the index I. For example, V might be a subset of I. In that case, the result is an array with the index(es) of V containing the corresponding elements of X. See the description in “Subscript(u1, i, u2)” for an example. The Subscript(x, i,v) function is the same as the subscript construct x[i=v], just using different syntax.

X[@I=n]: Slice construct

The slice construct has an @ sign before the index. It is different from the subscript construct in that it refers to the numerical position rather than the value of index I. It returns the n-th slice of X over index I:

X[@I=n]

The number n should be an integer between 1 (for the first element of index I) and Size(I) for the last element of I. If n is not an integer in this range, it returns NULL, and returns a warning (unless warnings have been turned off). Like the subscript construct, it can slice over multiple indexes, for example:

X[@I=n, @J=m]

You can mix slice and subscript operations in one expression:

X[@I=1, J=2, K=3]

The slice construct does just the same as the Slice(X, I, V) function (see “Slice(u, i, n)”), but with different syntax.

x[time-n]: Preceding time slice

x[Time-n] returns the value of variable x for the time period that is n time periods prior to the current time period. This function is only valid inside the Dynamic() function. See “Dynamic(initial1, initial2..., initialn, expr)” on page 298.

Subscript(u1, i, u2)

Returns the element or slice of array u1, for which index i has value u2. i must be an index of u1, and u2 must be value(s) of i.

If u2 is a single value, the result of Subscript() is an array indexed by all indexes of u1 except i. If u2 is an array, the result of Subscript() is also indexed by the indexes of u2.

If u1 is a single value, Subscript(u1, i, u2) returns u1.

Subscript(u1, i, u2) is equivalent to x[i = u2] when x is a variable identifier that evaluates to u1. Subscript() allows u1 to be an arbitrary expression.

Library Array

Examples To see the values in Cost corresponding to Mpg = 26:

Subscript(Cost, Mpg, 26) →

Car_type

<table>
<thead>
<tr>
<th>VW</th>
<th>Honda</th>
<th>BMW</th>
</tr>
</thead>
<tbody>
<tr>
<td>2185</td>
<td>2810</td>
<td>3435</td>
</tr>
</tbody>
</table>

Here u2 is an array of values:
Selecting, slicing, and subscripting arrays

Subscript(Cost, Car_type, ['VW', 'Honda']) → 
Car_type ▼, Mpg ▶

<table>
<thead>
<tr>
<th></th>
<th>26</th>
<th>30</th>
<th>35</th>
</tr>
</thead>
<tbody>
<tr>
<td>VW</td>
<td>2185</td>
<td>1705</td>
<td>1585</td>
</tr>
<tr>
<td>Honda</td>
<td>2810</td>
<td>2330</td>
<td>2210</td>
</tr>
</tbody>
</table>

Example of an arbitrary expression as the first parameter:

Subscript(Cost/12, Mpg, 26) → 
Car_type ▶

<table>
<thead>
<tr>
<th></th>
<th>VW</th>
<th>Honda</th>
<th>BMW</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>182.1</td>
<td>234.2</td>
<td>286.2</td>
</tr>
</tbody>
</table>

**Slice**

**Slice(u, i, n)**

Returns the element or cross-section of array u, for which index i has position n. i must be an index of u, and n must be an integer or array of integers between 1 and the length of i.

If n is an integer, the result of **Slice()** is an array indexed by all indexes of u except i. If n is an array, the result of **Slice()** is also indexed by the indexes of n.

If u is a scalar, **Slice(u, i, n)** returns u.

**Slice(u, n)**

If Slice has only two parameters, and u has a single dimension, it returns the nth element of u. For example:

Index Quarters := ‘Q’ & 1..4 
Slice(Quarters, 2) → ‘Q2’

This method is the only way to extract an element from an unindexed array, for example:

Slice(2000..2003, 4) → 2003

It also works to get the nth slice of a multidimensional array over an unindexed dimension, for example:

Slice(Quarters & ‘ ’ & 2000..2003, 4) → Array(Quarters, ['Q1 2003', 'Q2 2003', 'Q3 2003', 'Q4 2003'])

**Tip**

If a is a scalar, or if a is an array with two or more indexed dimensions and no unindexed dimensions, **Slice(a, n)** simply returns a.

**Library**

Array

**Examples**

Here, Analytica returns the values in Cost corresponding to the first element in Car_type, that is, the values of VW:
Selecting, slicing, and subscripting arrays

\[ \text{Slice(Cost, Car\_type, 1) \rightarrow Mpg} \]

Here, \( n \) is an array of positions:

\[ \text{Slice(Cost, Car\_type, \{1, 2\}) \rightarrow Mpg} \]

\[ \begin{array}{ccc}
26 & 30 & 35 \\
2185 & 1705 & 1585 \\
\end{array} \]

\[ \begin{array}{ccc}
1 & 2 & \\
2185 & 1705 & 1585 \\
2 & 2 & \\
2810 & 2330 & 2210 \\
\end{array} \]

\[ x[i = u] \]

Returns a specific element or slice of an array, where \( x \) is the identifier of an array variable, \( i \) is an index variable, and \( u \) is one or more elements of index \( i \) that corresponds to the desired array element. \( x[i = u2] \) is equivalent to \( \text{Subscript}(u1, i, u2) \) when \( x \) is a variable identifier that evaluates to \( u1 \).

\[ \text{Subscript}(x, i, u1) \text{ and } x[i=u1] \text{ just two ways to do the same thing.} \]

\[ \text{Library} \quad \text{Special} \]
\[ \text{Examples} \quad \text{Car\_prices[Car\_type = 'VW'] \rightarrow Years} \]

\[ \begin{array}{cccc}
8000 & 9000 & 9500 & 10K \\
\end{array} \]

\[ \text{Car\_prices[Car\_type = ['VW', 'Honda']] \rightarrow Years} \]

\[ \begin{array}{cccc}
\text{VW} & 8000 & 9000 & 9500 & 10K \\
\text{Honda} & 12K & 13K & 14K & 14.5K \\
\end{array} \]

You can specify more than one index when each index is given a single value.

\[ \text{Car\_prices[Car\_type = 'Honda', Years = 1986] \rightarrow 13K} \]

**Choice(i, n, inclAll)**

Appears as a popup menu in the definition field, allowing selection of the \( n \)th item from \( i \) (see “Creating a choice menu” on page 123). \( \text{Choice()} \) must appear at the topmost level of a definition. It cannot be used inside another expression. The optional \( \text{inclAll} \) parameter controls whether the "All" option (\( n=0 \)) appears on nucleoli popup (\( \text{inclAll} \) defaults to \( \text{True} \)).

\[ \text{Library} \quad \text{Array} \]
\[ \text{Examples} \quad \text{Choice(Years, 2) \rightarrow 1986} \]

If \( n=0 \), all values of \( i \) are returned:
Converting between multiD and relational tables

The MDArrayToTable() function "flattens" a multi-dimensional array into a two-dimensional relational table. The MDTable() function does the inverse, creating a multi-dimensional array from a table of values. Viewing tabular results in a multi-dimensional form via MDTable() often provides informative new perspective on existing data.

Many external application programs, including spreadsheets and relational databases, are limited to two-dimensional tables. Thus, when transferring multi-dimensional data between these applications and Analytica, it may be necessary to convert multi-dimensional data into two-dimensional tables before transferring.

MDArrayToTable(a, i, l)

Transforms a multi-dimensional array, a, into a two-dimensional array (i.e., a table) indexed by i and l. The result contains one row along i for each element of a. I must contain a list of names of the indexes of a, followed by one final element. All elements of l must be text values. The column corresponding to the final element of l contains the cell value. If l does not contain all the indexes of a, array abstraction will create a set of tables indexed by the dimensions not listed in l.

Before using MDArrayToTable(), you must define the index i with the appropriate number of elements. The number of elements in i may be either size(a), or the number of non-zero elements of a (in which case the resulting table will contain only the nonzero elements), otherwise an error results.

If the number of elements in i is equal to the number of non-zero elements of a, MDArrayToTable() acts like the inverse of MDTable() on a table that contains a row for only the nonzero elements of the array.

Library Array
Example

Rows := sequence(1,size(Cost_in_time))
Cols := ['Mpg','Time','Car_type','Cost']
MDArrayToTable(Cost_in_time,Rows,Cols) →
Rows ▼, Cols▼

<table>
<thead>
<tr>
<th>Mpg</th>
<th>Time</th>
<th>Car_type</th>
<th>Cost</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>26</td>
<td>0</td>
<td>VW</td>
</tr>
<tr>
<td>2</td>
<td>26</td>
<td>0</td>
<td>Honda</td>
</tr>
<tr>
<td>3</td>
<td>26</td>
<td>0</td>
<td>BMW</td>
</tr>
<tr>
<td>4</td>
<td>26</td>
<td>1</td>
<td>VW</td>
</tr>
<tr>
<td>5</td>
<td>26</td>
<td>1</td>
<td>Honda</td>
</tr>
<tr>
<td>6</td>
<td>26</td>
<td>1</td>
<td>BMW</td>
</tr>
<tr>
<td>7</td>
<td>26</td>
<td>2</td>
<td>VW</td>
</tr>
<tr>
<td>...</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>45</td>
<td>35</td>
<td>4</td>
<td>BMW</td>
</tr>
</tbody>
</table>
**MDTable(t, rows, cols, vars, conglomFn, missingVal)**

Returns a multi-dimensional array from a two-dimensional table of values. `t` is a two-dimensional array (i.e., a table) indexed by `rows` and `cols`. Each row of `t` specifies the coordinates of a cell in a multi-dimensional array, along with the value for that cell.

The dimensions of the final result are given by the optional parameter `vars`. `vars` must be a list of index identifiers or index names. The length of `cols` must be one greater than the length of `vars`.

If `vars` is omitted, the dimensions of the final result are specified by the first `n-1` elements of `cols`, where `(n=size(cols))`. In this case, the elements of `cols` must be index identifiers or index names.

The first `n-1` columns of `t` specify the coordinates of a cell in the result. The final column of `t` specifies the value for the indicated cell.

Before using `MDTable()`, you must define all of the indexes for the result. Each index must include all values that occur in the corresponding column of `t` or an error will result. The `Unique()` function is useful for defining the necessary indexes.

It is possible that two or more rows of `t` specify identical coordinates. In this case, a conglomeration function is used to combine the values for the given cell. The `conglomFn` parameter is a text value specifying which conglomeration function is to be used. Possible values are: "sum" (default), "min", "max", "average", or "product".

It is also possible that no row in `t` corresponds to a particular cell. In this case, the cell value is set to `missingVal`, or if the `missingVal` parameter is omitted, the cell value is set to `undefined`. `Undefined` values can be detected using the `IsUndef()` function.

**Library**  Array

**Example**  Suppose `T`, `Rows`, and `Cols` are defined as indicated by the following table:

<table>
<thead>
<tr>
<th>Car_type</th>
<th>Mpg</th>
<th>X</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>VW</td>
<td>26</td>
</tr>
<tr>
<td>2</td>
<td>VW</td>
<td>30</td>
</tr>
<tr>
<td>3</td>
<td>Honda</td>
<td>26</td>
</tr>
<tr>
<td>4</td>
<td>Honda</td>
<td>35</td>
</tr>
<tr>
<td>5</td>
<td>BMW</td>
<td>30</td>
</tr>
<tr>
<td>6</td>
<td>BMW</td>
<td>35</td>
</tr>
<tr>
<td>7</td>
<td>BMW</td>
<td>35</td>
</tr>
</tbody>
</table>

`MDTable(T, Rows, Cols, [Car_type, Mpg],
average, ‘n/a’)` →

<table>
<thead>
<tr>
<th>Car_type</th>
<th>Mpg</th>
</tr>
</thead>
<tbody>
<tr>
<td>VW</td>
<td>2185</td>
</tr>
<tr>
<td>Honda</td>
<td>2330</td>
</tr>
<tr>
<td>BMW</td>
<td>2955</td>
</tr>
</tbody>
</table>

Notice that in the example, Rows 6 and 7 both specified values for `Car_type=BMW, Mpg=35`. The 'average' conglomeration function was used to combine these.
Interpolation functions

Analytica includes three functions that interpolate across arrays. The graph below is a simple comparison of the three.

The first two examples use the following variables:

- **Index_a:**
  - a
  - b
  - c

- **Index_b:**
  - 1
  - 2
  - 3

- **Array_a:**
  - Index_a ▼, Index_b ▼
  - | 1 | 2 | 3 |
  - | a | 7 | -3 | 1 |
  - | b | -4 | -1 | 6 |
  - | c | 5 |  0 | -2 |

**Cubicinterp(d, r, x, i)**

Returns the natural cubic spline interpolated values of r along d, interpolating for values of x. d and r must both be indexed by i, and d must be increasing along i.

For each value of x, **Cubicinterp()** finds the nearest values from d, and using a natural cubic spline between the corresponding values of r, computes the interpolated value. If x is less than the minimum value in d, it returns the first value in r; if x is greater than the maximum value in d, it returns the last value for r.

**Library** Special

**Example**

```
Cubicinterp(Index_b, Array_a, 1.5, Index_b) →
```

<table>
<thead>
<tr>
<th>a</th>
<th>b</th>
<th>c</th>
</tr>
</thead>
<tbody>
<tr>
<td>0.6875</td>
<td>-2.875</td>
<td>2.219</td>
</tr>
</tbody>
</table>
Linearinterp(d, r, x, i)

Returns linearly interpolated values of x, given r representing an arbitrary piecewise linear function. d and r must both be indexed by i, and d must be increasing along i. r is an array of the corresponding output values for the function (not necessarily increasing and may be more than one dimension). x may be probabilistic and/or an array.

For each value of x, Linearinterp() finds the nearest two values from d and interpolates linearly between the corresponding values from r. If x is less than the minimum value in d, it returns the first value in r. If x is greater than the maximum value in d, it returns the last value in r.

Library  Special
Example  Linearinterp(Index_b, Array_a, 1.5, Index_b) → 
Index_a ▶

<table>
<thead>
<tr>
<th>a</th>
<th>b</th>
<th>c</th>
</tr>
</thead>
<tbody>
<tr>
<td>2</td>
<td>-2.5</td>
<td>2.5</td>
</tr>
</tbody>
</table>

Stepinterp(d, a, x, i)

Returns the element or slice of array a for which d has the smallest value that is greater than or equal to x. d and a must both be indexed by i, and d must be increasing along index i. If x is greater than all values of d, it returns the element for which d has the largest value.

When an optional parameter, LeftLookup, is specified as True, it returns the element or slice of a corresponding to the largest value in d that is less than or equal to x.

If x is a single value, the result of Stepinterp() is an array indexed by all indexes of a except d’s index. If x is an array, the result of Stepinterp() is also indexed by the indexes of x.

Stepinterp() is similar to Subscript(u1, i, u2); however, Subscript() selects based on the index value being equal to x, while Stepinterp() selects based on the array value being greater than or equal to x.

Stepinterp() can be used to perform table lookup.

Library  Special
Examples  To see the values in Cost corresponding to Mpg >= 33:
Stepinterp(MPG, Cost, 33, MPG) → 
Car_type ▶

<table>
<thead>
<tr>
<th>VW</th>
<th>Honda</th>
<th>BMW</th>
</tr>
</thead>
<tbody>
<tr>
<td>1585</td>
<td>2210</td>
<td>2835</td>
</tr>
</tbody>
</table>

Here x is an array of values:

Stepinterp(MPG, Cost, [28, 33], MPG) → 

<table>
<thead>
<tr>
<th>VW</th>
<th>Honda</th>
<th>BMW</th>
</tr>
</thead>
<tbody>
<tr>
<td>28</td>
<td>1705</td>
<td>2330</td>
</tr>
<tr>
<td>33</td>
<td>1585</td>
<td>2210</td>
</tr>
</tbody>
</table>
Other array functions

**Concat(a1, a2, i, j, k)**

Appends array a2 to array a1. i and j are indexes of a1 and a2, respectively. k is the index of the resulting dimension, and usually consists of the list created by concatenating i and j.

a1 and a2 must have the same number of dimensions. If they are one-dimensional, the parameters i, j, and k are optional. If they are not specified, the resulting array is unindexed.

If a1 and a2 are multidimensional, they must have the same non-concatenated indexes.

**Library** Array

**Examples**

In addition to the variables defined in “Example data”, these examples use the following:

**More_years**:

**All_years**:

**More_prices**: Car_type ▼, More_years ▼

| VW   | 11K  | 12K  | 12.5K |
| Honda| 15K  | 15.5K| 16.5K |
| BMW  | 23.5K| 25K  | 27K   |

Concat(Years, More_years) →

Concat ▼

**Sequence2**: Sequence(1,7)

Concat(Years, More_years, Years, More_years, Sequence2) →

Sequence2 ▼

<td>12.5K</td>
<td>16.5K</td>
<td>27K</td>
</tr>
</tbody>
</table>

**ConcatRows(A : Array[I,J] ; I,J,K : Index)**

Takes an array, A indexed by I and J, and concatenates each row, flattening the array by one dimension. The result is indexed by *ResultIndex*, which must be an index with \( \text{size}(I) \times \text{size}(J) \) elements.

**Library**

Concatenation.ana

To use this function, you must add the library to your model.

**IndexNames(a)**

Returns a list of the names of the indexes of the array a.

**Library**

Array

**Example**

```plaintext
IndexNames(Car_prices)  \rightarrow [\text{Car_type'}, \text{Years'}]
```

**IndexesOf(A : Array)**

Returns a list of handles, each one serving as a handle to the indexes of array A.

This is similar to **IndexNames(A)**, except that **IndexesOf** returns actual handles, while **IndexNames** returns the index identifiers (as text strings).

It is possible for an array to have more than one local index having identical names. Obviously, this is not recommended, but in the unusual case where this occurs, the index handles returned by **IndexesOf** are unambiguous.

**Library**

Array

**Example**

```plaintext
IndexesOf(Car_prices)  \rightarrow [\text{Car_type'}, \text{Years'}]
```

**IndexValue(I)**

Returns the index value for the given variable or index I. Some variables have both an index value and a result value. Examples include a self-indexed array; a variable or index defined as a list of identifiers or list of expressions; and a **Choice** list with a self-domain. **IndexValue(I)** returns the index value of I, where (I) alone would return its result value.

**Library**

Array Functions

**Details**

The **IndexValue** function, if it weren’t built-in, could easily be defined within Analytica 4.0 as:

```plaintext
Function IndexValue(I : IndexType) := I
```

This definition, however, requires Analytica 4.0 or later.
Example

Index \( L := [I,J,K,"value"] \)
Index rows := 1..Size(A)
Variable Flat_A := MdArrayToTable( A, rows, IndexValue(L) )

Size(u)

Returns the number of array elements of \( u \).

Library Array

Examples

Size(Years) \( \rightarrow 4 \)
Size(Car_prices) \( \rightarrow 12 \)
Size(10) \( \rightarrow 1 \)

SubTable

The \texttt{SubTable} function allows a subset of another edit table to be edited by the user as a different view. To the user, it appears as if he is editing any other edit table; however, the changes are stored in the original edit table. The rows and columns can be transformed to other dimensions in the \texttt{SubTable}, with different index element orders, based on \texttt{Subset} indexes, and with different number formats.

\texttt{SubTable(v[i = x])}

\texttt{SubTable} lets you treat a slice of table \( a \) as an edit table, where variable \( v \) is defined as an edit table, probability table, determtable, or another subtable. It lets a model offer alternative editable views of the same input data.

\texttt{SubTable} must appear as the top-level function in an expression. It must contain a slice or subscript operator. For example, in the simplest form:

\[ \texttt{SubTable( A[I=J] )} \]

where \( J \) is an index containing a subset of the elements of \( I \), and \( A \) is a variable containing an edit table, probability table, or determtable. Many other variations are also useful including:

\[ \texttt{SubTable( A[I=x] )} \]
\[ \texttt{SubTable( A[I1=J1,I2=J2] )} \]
\[ \texttt{SubTable( A[I=B] )} \]
\[ \texttt{SubTable( A[@I=C] )} \]

where \( x \) is a scalar, and \( B \) and \( C \) are an array indexed by \( J \).

\textbf{ADE and Analytica Web Player}

At present, ADE and AWP do not recognize subtables. Thus, in ADE you cannot (yet) obtain a \texttt{DefTable} for a variable defined using \texttt{SubTable}. This enhancement may be added in the future. In the Analytica Web Player, \texttt{SubTable} definitions do not allow editing in table mode.

Matrix functions

Matrix functions perform matrix operations. In Analytica, a \textit{matrix} is defined as a two-dimensional array of numbers.
Dot product of two matrices

The dot product (i.e., matrix multiplication) of MatrixA and MatrixB is equal to

\[ \text{Sum}(\text{MatrixA} \times \text{MatrixB}, i) \]

where \( i \) is the common index.

Example  MatrixA:

\[
\begin{array}{ccc}
1 & 2 & 3 \\
\text{a} & 4 & 1 & 2 \\
\text{b} & 2 & 5 & 3 \\
\text{c} & 3 & 2 & 7 \\
\end{array}
\]

MatrixB:

\[
\begin{array}{ccc}
1 & 2 & 3 \\
\text{l} & 3 & 2 & 1 \\
\text{m} & 2 & 5 & 3 \\
\text{n} & 4 & 1 & 2 \\
\end{array}
\]

\[ \text{Sum}(\text{MatrixA} \times \text{MatrixB}, i) \rightarrow \]

\[
\begin{array}{ccc}
a & b & c \\
l & 16 & 19 & 20 \\
m & 19 & 38 & 37 \\
n & 21 & 19 & 28 \\
\end{array}
\]

MatrixMultiply(a:Numeric all[aRow,aCol]; aRow, aCol:Index; b:Numeric all[bRow,bCol]; bRow, bCol:Index)

Performs a matrix multiplication on matrix a, having indexes aRow and aCol, and matrix b, having indexes bRow and bCol. The result is indexed by aRow and bCol. a and b must have the specified two indexes, and may also have other indexes. bCol and bRow must have the same length or it flags an error. If bRow and bCol are the same index, it returns only the diagonal of the result.

Library  Matrix

Example  Matrices

\[
\begin{array}{ccc}
\text{index1} & \text{index2} \\
1 & 1 & 2 \\
2 & 1 & 0 \\
\end{array}
\]

\[
\begin{array}{ccc}
\text{index2} & \text{index3} \\
1 & 3 & 0 & 1 \\
2 & 0 & 1 & 1 \\
\end{array}
\]

\[ \text{MatrixMultiply}(C,\text{index1},\text{index2},D,\text{index2},\text{index3}) \rightarrow \]
index1 ▼, index3 ▶

<table>
<thead>
<tr>
<th></th>
<th>1</th>
<th>2</th>
<th>3</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>3</td>
<td>2</td>
<td>3</td>
</tr>
<tr>
<td>2</td>
<td>3</td>
<td>0</td>
<td>1</td>
</tr>
</tbody>
</table>

When the inner index is shared by \( C \) and \( D \), the expression \( \text{Sum}(C \cdot D, \text{index2}) \) is equivalent to their dot product (see “Dot product of two matrices”).

**Tip**

The way to multiply a matrix by its transpose is:

\[
\text{MatrixMultiply}( A, I, J, \text{Transpose}(A,I,J), I, J )
\]

It does not work to use \( \text{MatrixMultiply}(A,I,J,A,J,I) \) because the result would have to be doubly indexed by \( I \).

---

### Transpose(c, i, j)

Returns the transpose of matrix \( c \) along dimensions \( i \) and \( j \).

**Library** Matrix

**Example**

\[
\text{Transpose}(\text{MatrixA}, i, j) \rightarrow \\
\text{\( j \)} ▼, \text{\( i \)} ▶
\]

<table>
<thead>
<tr>
<th></th>
<th>1</th>
<th>2</th>
<th>3</th>
</tr>
</thead>
<tbody>
<tr>
<td>( a )</td>

<tr>
<td>( b )</td>
<td>1</td>
<td>5</td>
<td>2</td>
</tr>
<tr>
<td>( c )</td>
<td>2</td>
<td>3</td>
<td>7</td>
</tr>
</tbody>
</table>

### Invert(c, i, j)

Returns the inversion of matrix \( c \) along dimensions \( i \) and \( j \).

**Library** Matrix

**Example**

Set number format to fixed point, 3 decimal digits.

\[
\text{Invert}(\text{MatrixA}, i, j) \rightarrow \\
\text{\( j \)} ▼, \text{\( i \)} ▶
\]

<table>
<thead>
<tr>
<th></th>
<th>1</th>
<th>2</th>
<th>3</th>
</tr>
</thead>
<tbody>
<tr>
<td>( a )</td>
<td>0.326</td>
<td>-0.034</td>
<td>-0.079</td>

</tr>
<tr>
<td>c</td>
<td>3</td>
<td>2</td>
<td>7</td>
</tr>
</tbody>
</table>

Determinant (MatrixA, i, j) → 89

Decompose(c, i, j)

Returns the Cholesky decomposition (square root) matrix of matrix c along dimensions i and j. Matrix c must be symmetric and positive-definite. (Positive-definite means that \( \mathbf{v} \cdot \mathbf{c} \cdot \mathbf{v} > 0 \), for all vectors \( \mathbf{v} \).)

Cholesky decomposition computes a lower diagonal matrix \( \mathbf{L} \) such that \( \mathbf{L} \cdot \mathbf{L}' = \mathbf{c} \), where \( \mathbf{L}' \) is the transpose of \( \mathbf{L} \).

EigenDecomp(a:Numeric[i, j]; i, j:Index)

Computes the Eigenvalues and Eigenvectors of a square, symmetric matrix a indexed by i and j. EigenDecomp() returns a result indexed by j and .item (where .item is a temporary index with two elements: ['value','vector']). Each column of the result contains one Eigenvalue/Eigenvector pair. The Eigenvalue is a number, the Eigenvector is a reference to a rows-indexed Eigenvector. If result is the result of evaluating EigenDecomp(), then the Eigenvalues are given by result[.item='value'], and the Eigenvectors are given by #result[.item='vector']. Each Eigenvector is indexed by i.

Given a square matrix a, a non-zero number (\( \lambda \)) is called an Eigenvalue of a, and a non-zero vector \( \mathbf{x} \) the corresponding Eigenvector of a when
\[ a \cdot x = \lambda \cdot x \]

An \( N \times N \) matrix will have \( N \) (not-necessarily unique) Eigenvalue-Eigenvector pairs. When \( a \) is a symmetric matrix, the Eigenvalues and Eigenvectors are real-valued. Eigen-analysis is widely used in Engineering and statistics.

**Tip**
The matrix \( a \) must be square and symmetric. Mathematically, Eigen decompositions do exist for square non-symmetric matrices, but the algorithm used here is limited only to symmetric matrices, since symmetric decompositions are guaranteed to be real-valued, while, in general, Eigen decompositions may be complex.

```

SingularValueDecomp(a, i, j, j2)

**SingularValueDecomp()** (Singular Value Decomposition) is often used with sets of equations or matrices that are singular or ill-conditioned (that is, very close to singular). It factors a matrix \( a \), indexed by \( i \) and \( j \), with \( \text{size}(i) = \text{size}(j) \), into three matrices, \( U \), \( W \), and \( V \), such that

\[
a = U \cdot W \cdot V
\]  \hspace{1cm} (1)

where \( U \) and \( V \) are orthogonal matrices and \( W \) is a diagonal matrix. \( U \) is dimensioned by \( i \) and \( j \), \( W \) by \( j \) and \( j2 \), and \( V \) by \( j \) and \( j2 \). In Analytica notation:

```
Variable A :=
    Sum(Sum(U*W,J) * Transpose(V,J,J2), J2)
```

The index \( j2 \) must be the same size as \( j \) and is used to index the resulting \( W \) and \( V \) arrays.
**SingularValueDecomp()** returns an array of three elements indexed by a special system index named **SvdIndex** with each element, \( u, w, \) and \( v \), being a reference to the corresponding array. Use the ‘\#' (dereference) operator to obtain the matrix value from each reference, as in:

```
Index J2
Definition: CopyIndex(J)
```

```
Variable SvdResult
Definition: SingularValueDecomp(A, I, J, J2)
```

```
Variable U
Definition: #SvdResult[SvdIndex='U']
```

```
Variable W
Definition: #SvdResult[SvdIndex='W']
```

```
Variable V
Definition: #SvdResult[SvdIndex='V']
```

**Tip** Like most other matrix functions, **SingularValueDecomp()** requires its main parameter to be square, and will not work if indexes \( i \) and \( j \) are not the same size.
This chapter describes a variety of useful functions from built-in and added libraries:

- Text functions that work with text values, to transform, search, split, and join them; see “Text functions”.
- Date functions for working with date numbers; see “Date functions”.
- Advanced math functions; see “Advanced math functions”.
- Built-in financial functions; see “Financial functions”.
- A library of extra financial functions, including functions for valuing options; see “Financial library functions”.
- Advanced probability functions; see “Advanced probability functions”.
Text functions

These functions work with **text values** (sometimes known as **strings**), available in the built-in Text library. See “Text values”.

**Asc(t)**  
Returns the ASCII code (a number between 0 and 255) of the first character in text value `t`. This is occasionally useful, for example to understand the alphabetic ordering of text values.

**Chr(n)**  
Returns the character corresponding to the numeric ASCII code `n` (a number between 0 and 255). `Chr()` and `Asc()` are inverses of each other, for example:

```
Chr(65) → 'A',    Asc(Chr(65)) → 65
```

```
Asc('A') → 65,    Chr(Asc('A')) → 'A'
```

`Chr()` is useful for creating characters that cannot easily be typed, such as **Tab**, which is `Chr(9)` and **carriage return (CR)**, which is `Chr(13)`. For example, if you read in a text file, `x`, you can use `SplitText(x, Chr(13))` to generate an array of lines from a multi-line text file.

**TextLength(t)**  
Returns the number of characters in text `t`.

```
TextLength('supercalifragilisticexpialidocious') → 34
```

**SelectText(t, m, n)**  
Returns text containing the `m`th through the `n`th character of text `t` (where the first character is `m`=1). If `n` is omitted it returns characters from the `m`th through the end of `t`.

```
SelectText('One or two', 1, 3) → 'One'
SelectText('One or two', 8) → 'two'
```

**FindinText(t1, t2, start)**  
Returns the position of the first occurrence of the text `t1` within the text `t2`, as the number of characters to the first character of `t1`. If `t1` does not occur in `t2`, it returns 0. **FindinText()** is case-sensitive. For example:

```
Variable People := 'Amy, Betty, Carla'
FindinText('Amy', People) → 1
FindinText('amy', People) → 0
FindinText('Betty', People) → 6
FindinText('Fred', People) → 0
```

The optional third parameter, `start`, specifies the position to start searching at, for example, if you want to find a second occurrence of `t1` after you have found the first one.

```
FindinText('i', 'Supercalifragilisticexpialidocious') → 9
FindinText('i', 'Supercalifragilisticexpialidocious', 10) → 14
```

**TextReplace(t, t1, t2, all)**  
If `all` is omitted or `false`, it returns text `t` with the first occurrence of text `t1` replaced by `t2`. If `all` is true, it returns text `t` with all occurrences of text `t1` replaced by `t2`.

```
TextReplace('StringReplace, StringLength', 'String', 'Text')
→ 'TextReplace, StringLength'
TextReplace('StringReplace, StringLength', 'String', 'Text', True)
→ 'TextReplace, TextLength'
```

**Joining Text: a & b**  
The "&" operator joins (concatenates) two text values to form a single text value, for example:

```
'What is the' & ' number' & '?'
→ 'What is the number?'`
If one or both operands are numbers, it converts them to text using the number format of the variable whose definition contains this function call (or the default suffix format if none is set), for example:

\[
\text{‘The number is ‘ } & 10^8 \rightarrow \text{ ‘The number is 100M’}
\]

This is also useful for converting (or "coercing") numbers to text.

JoinText(a, index, separator, finalSeparator)

Returns the elements of array a joined together into a single text value over index i. If elements of a are numeric, they are first converted to text using the number format settings for the variable whose definition contains this function call. For example:

\[
\begin{align*}
I & : \{‘A’, ‘B’, ‘C’\} \\
\text{JoinText}(I, I) & \rightarrow ‘ABC’ \\
A & : \text{Array}(I, \{‘VW’, ‘Honda’, ‘BMW’\}) \\
\text{JoinText}(A, I) & \rightarrow ‘VWHondaBMW’
\end{align*}
\]

If the optional parameter separator is specified, it is inserted as a separator between successive elements, for example:

\[
\text{JoinText}(A, I, ‘,’ ) \rightarrow ‘VW, Honda, BMW’
\]

The optional parameter finalSeparator, if present, specifies a different separator between the second-to-last and last elements of a.

\[
\text{JoinText}(A, I, ‘,’ , ‘and’ ) \rightarrow ‘VW; Honda; and BMW’
\]

SplitText(t, separator)

Returns a list of text values formed by splitting the elements of text value t at each occurrence of separator. For example:

\[
\begin{align*}
\text{SplitText}(‘VW, Honda, BMW’, ‘,’ ) & \rightarrow \{‘VW’, ‘Honda’, ‘BMW’\}
\end{align*}
\]

SplitText() is the inverse of JoinText(), if you use the same separators. For example:

\[
\begin{align*}
\text{Var x:=SplitText(‘Humpty Dumpty sat on a wall.’, ‘ ‘)} \\
\text{JoinText( x, , ‘ ‘ )} & \rightarrow ‘Humpty Dumpty sat on a wall.’
\end{align*}
\]

Tip

With SplitText(), t must be a single text value, not an array. Otherwise, it might generate an array of arrays of different length. See “Functions expecting atomic parameters” on what to do if you want apply it to an array.

TextLowerCase(t)

Returns the text t with all letters as lowercase. For example:

\[
\begin{align*}
\text{TextLowerCase(‘What does XML mean?’)} & \rightarrow ‘what does xml mean?’
\end{align*}
\]

TextUpperCase(t)

Returns the text t with all letters as uppercase. For example:

\[
\begin{align*}
\text{TextUpperCase(‘What does XML mean?’)} & \rightarrow ‘WHAT DOES XML MEAN?’
\end{align*}
\]

TextSentenceCase

Returns the text t with the first character (if a letter) as uppercase, and any other letters as lowercase. For example:

\[
\begin{align*}
\text{TextSentenceCase(‘mary ann FRED Maylene’) } & \rightarrow ‘Mary ann fred maylene’ \\
\text{TextSentenceCase(SplitText(‘mary ann FRED Maylene’, ‘ ’))} & \rightarrow \{‘Mary’, ‘Ann’, ‘Fred’, ‘Maylene’\}
\end{align*}
\]
**Date functions**

These functions work with *date numbers* — that is, the number of days since the *date origin*, usually Jan 1, 1904. See “Date numbers and the date origin”. Date numbers display as dates if you select a date number format. **MakeDate()** generates a date number from the year, month, and day. **DatePart** extracts the year, month, or day from a date number. **DateAdd()** adds a number of days, weeks, months, or years to a date. And **Today()** returns today's date.

### MakeDate(year, month, day)

Gives the date value for the date with given *year*, *month*, and *day*. If omitted, *month* and *day* default to 1. Parameters must be positive integers.

**Examples**

- MakeDate(2007, 5, 15) → 15-May-2007
- MakeDate(2000) → 1-Jan-2000

### DatePart(date, part)

Given a date value *date*, it returns the year, month, or day as a number, according to the value of *part*, which must be an uppercase character:

- 'Y' gives the four digit year as a number, such as 2006.
- 'M' gives the month as a number between 1 and 12.
- 'D' gives the day as a number between 1 and 31.
- "W" gives the day of the week as a number from 1 (Sunday) to 7 (Saturday).

Other options for *part* are: 'MMM' → 'Jan', 'MMMM' → 'January', 'ddd' → '1st', 'dddd' → 'first', 'Dddd' → 'First', 'www' → 'Mon', 'wwww' → 'Monday', 'q' → 1 to 4 for number of quarter of the year.

**Examples**

- DatePart(MakeDate(2006, 2, 28), 'D') → 28

This makes a sequence of all weekdays between **Date1** and **Date2**:

Index J := Date1 .. Date2;
Subset(DatePart(J, "W") >= 2 AND DatePart(J, "W") <= 6 )

### DateAdd(date, n, unit)

Given a date value *date*, it returns a date value offset by *n* years, months, days, or weekdays according to whether *unit* is 'Y', 'M', 'D', or 'WD'. If *n* is negative, it subtracts units from the date.

**Examples**

**DateAdd** is especially useful for generating a sequence of dates, e.g., weeks, months, or quarters, for a time index:
Advanced math functions

The inverse trigonometric functions. For each the parameter x is between 0 and 1, and the result is in degrees. \text{Arccos} returns a result between 0 and 180 degrees:

\begin{align*}
\text{Arccos}(1) & \rightarrow 0 \\
\text{Arccos}(\cos(45)) & \rightarrow 45
\end{align*}

\text{Arcsin} returns a result between -90 and 90 degrees:

\begin{align*}
\text{Arcsin}(1) & \rightarrow 90 \\
\text{Arcsin}(\sin(45)) & \rightarrow 45
\end{align*}

\text{Arctan2} gives the arctangent of \text{y/x} without losing information about which quadrant the point is in. The result is the angle in degrees between the X axis and the point (x,y) in the two dimensional plane, in the range (-180,180):

\begin{align*}
\text{Arctan2}(-1,1) & \rightarrow -45 \\
\text{Arctan2}(0,-1) & \rightarrow 180 \\
\text{Arctan2}(0,0) & \rightarrow 0
\end{align*}

The hyperbolic cosine, sine, and tangent of \text{x, x} assumed to be in degrees.

\begin{align*}
\text{Cosh}(0) & \rightarrow 1 \\
\text{Sinh}(0) & \rightarrow 0 \\
\text{Tanh}(\text{INF}) & \rightarrow 1
\end{align*}
Lgamma(x) Returns the Log Gamma function of x. Without numeric overflow, this function is equivalent to \( \ln(\text{GammaFn}(x)) \). Because the gamma function grows so rapidly, it is often much more convenient to use LGamma() to avoid numeric overflow.

LGamma(10) \rightarrow 12.8

Financial functions

These functions can be accessed under the Definition menu Financial command, or in the Object Finder dialog box, Financial library. The function names and parameters match those in Microsoft Excel, where they are equivalent. Of course, the Analytica versions support array abstraction, which makes them more flexible.

Parameters

The same parameters occur in many of the financial functions. These parameters are described here. Dollar amounts for both parameters and return values of functions are expressed as the amount you receive. If you make a payment, the amount is negative. If you receive a payment, the amount is positive.

rate The interest rate per period. For example, if periods are months, the rate should be adjusted to the monthly rate, not the annual rate (e.g., \(8\%/12\), or \(1.08^{(1/12)}-1\) with monthly compounding).

nPer Number of periods in the lifetime of an annuity.

per The period (between 1 and nPer) being computed.

pv The present value of the annuity. For example, for a loan this is the loan amount (positive if you receive the loan, negative if you are the lender).

fv The future value of the annuity. This is the remaining value of the annuity after the final payment. In the case of a loan, for example, this is the balloon payment at the end (positive if you are the lender, negative if you pay the balloon amount). This parameter is usually optional with a default value of zero.

pmt The total payment per period (interest + principal). If you receive payments, this is positive. If you make payments, this is negative.

type Indicates whether payments are due at the beginning or end of each period.

True Payments are due at the beginning of each period, with the first payment due immediately.

False (default) Payments are due at the end of each period.

Cumipmt(rate, nPer, pv, startPeriod, endPeriod, type )

Returns the cumulative interest paid on an annuity between, and including, startPeriod (shown as sp in equation below) and endPeriod (shown as ep in equation below). The annuity is assumed to have a constant interest rate and periodic payments. This is equal to:
Financial functions

Example  Interest payments during the first year on a $100,000 loan at 8% is:

\[
\text{CumIPmt}(8\%/12, 360, 100K, 1, 12) \rightarrow -7,969.81
\]

The result is negative since these are payments.

\[\sum_{n = sp}^{ep} Ipmt(rate, nPer, Pv, 0, Type)\]

Cumprinc(rate, nPer, pv, startPeriod, endPeriod, type)

Returns the cumulative principal paid on an annuity between, and including, startPeriod (shown as sp in equation below) and endPeriod (shown as ep in equation below). The annuity is assumed to have a constant interest rate and periodic payments. The result is equal to:

\[
\sum_{n = sp}^{ep} PPmt(Rate, nPer, Pv, 0, Type)
\]

Example  The total principal paid during the first year on a $100,000 loan at 8% is:

\[
\text{CumPrinc}(8\%/12, 360, 100K, 1, 12) \rightarrow -835.36
\]

The result is negative since these are payments.

Fv(rate, nPer, pmt, pv, type)

Returns the future value of an annuity investment with constant periodic payments and fixed interest rate. The result is positive if you receive money at the end of the annuity’s lifetime, and negative if you must make a payment at the end of the annuity’s lifetime.

Examples You invest $1000 in an annuity that pays 6% annual interest, compounded monthly (0.5% per month), that pays out $50 at the end of each month for 12 months, and then refunds whatever is left after 12 months. The amount refunded is:

\[
Fv(0.5\%, 12, 50, -1000) \rightarrow $444.90
\]

You borrow $50,000 at a fixed annual rate of 12% (1% per month). You make monthly payments of $550 for 15 years, and then pay off the remaining balance in a single balloon payment. That final balloon payment is (the negative is because it is a payment for you):

\[
-Fv(1\%, 15*12, -550, 50000) \rightarrow $25,020.99
\]

You open a fixed-rate bank account that pays 0.5% per month in interest. At the beginning of each month (including when you open the account) you deposit $100. The amount in the account at the end of the each of the first three years is:

\[
Fv(0.5\%, [12, 24, 36], -100, 0, True) \rightarrow
\]
Financial functions

Ipmt(rate, per, nPer, pv, fv, type)

Returns the interest portion of a payment on an annuity, assuming constant period payments and fixed interest rate.

Example

The interest you pay in the 24th month on a 30-year fixed $100K loan at an 8%/12 monthly interest rate is (the result of IPmt is negative since this is a payment for you):

\[-\text{IPmt}(8\%/12, 24, 12 \times 30, 100K) \rightarrow 655.59\]

Irr(values, i, guess)

Returns the internal rate of return (IRR) of a series of periodic payments (negative values) and inflows (positive values). The IRR is the discount rate at which the net present value (NPV) of the flows is zero. The array values must be indexed by i.

If the cash flow never changes sign, Irr() will have no solution and returns NaN (not a number). If a cash flow changes sign more than once, Irr() may have multiple solutions, and will return the first solution found. The implementation uses an iterative gradient-descent search to locate a solution. The optional argument, guess, can be provided as a starting value for the search (default is 10%). When there are multiple solutions, the one closest to guess will usually be returned. If no solution is found within 30 iterations, Irr() returns NaN.

To compute the IRR for a non-periodic cash flow, use XIRR().

Example

Earnings: Time

<table>
<thead>
<tr>
<th>1999</th>
<th>2000</th>
<th>2001</th>
<th>2002</th>
<th>2003</th>
<th>2004</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1M</td>
<td>-500K</td>
<td>-100K</td>
<td>100K</td>
<td>1M</td>
<td>2M</td>
</tr>
</tbody>
</table>

\[\text{Irr}(\text{Earnings, Time}) \rightarrow 17.15\%\]

Nper(rate, pmt, pv, fv, type)

Returns the number of periods of an annuity with constant periodic payments and fixed interest rate.

Example

You invest $10,000 in an annuity that pays 8% annually. Each year you withdraw $1,000. Your annuity will last for:

\[\text{NPer}(8\%, 1000, -10K) \rightarrow 20.91 \text{ (years)}\]

Npv(discountRate, values, i)

Returns the net-present value of a cash flow with equally spaced periods. The values parameter contains a series of periodic payments (negative values) and inflows (positive values), indexed by i. Future values are discounted by discountRate per period. The NPV is given by:

\[
\sum_{j=1}^{n} \frac{\text{Values}[i=j]}{(1 + \text{DiscountRate})^j}
\]
Financial functions

**Tip**
The first value is discounted as if it is one step in the future. To compute the NPV for a non-periodic cash flow, use `Xnpv()`.

### Example
**Earnings: Time**

<table>
<thead>
<tr>
<th>Year</th>
<th>1999</th>
<th>2000</th>
<th>2001</th>
<th>2002</th>
<th>2003</th>
<th>2004</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>1M</td>
<td>-500K</td>
<td>100K</td>
<td>1M</td>
<td>2M</td>
<td></td>
</tr>
</tbody>
</table>

At a discount rate of 5%, the net present value of this cash flow is:

\[
\text{Npv}(\ 5\%, \ \text{Earnings}, \ \text{Time}) \to \$865,947.76
\]

**Pmt(rate, nPer, pv, fv, type)**

Returns the total payment per period (interest + principal) for an annuity with constant periodic payments and fixed interest rate.

**Example**
You obtain a 30-year fixed mortgage at 8%/12 per month for $100K. Your monthly payment will be (note that the result of `Pmt()` is negative since this is a payment for you):

\[
-Pmt(\ 8%/12, \ 30*12, \ 100K) \to \$733.76
\]

**Ppmt(rate, per, nPer, pv, fv, type)**

Returns the principal portion of a payment on an annuity with constant period payments and fixed interest rate.

**Example**
You have a 30-year fixed $100K loan at a rate of 8%/12 monthly. On your 24th payment, the amount of your payment that goes towards principal is (note that the result of `PPmt()` is negative since this is a payment for you):

\[
-PPmt(8%/12, \ 24, \ 12*30, \ 100K) \to \$78.18
\]

**Pv(rate, nPer, pmt, fv, type)**

Returns the present value of an annuity. The annuity is assumed to have constant periodic payments to you of `pmt` per period for `nPer` periods, with a return of `rate` per period.

**Example**
To receive $100 per month from an annuity that returns 6%/12 per month for the next 10 years, you would need to invest (note that the result from `Pv()` is negative since you are paying to make the investment):

\[
-Pv(6%/12, \ 10*12, \ 100) \to \$9,007.35
\]

**Rate(nPer, pmt, pv, fv, type, guess)**

Returns the interest rate (per period) for an annuity. The value returned is the interest rate that results in equal payments of `pmt` per period over the `nPer` periods of the annuity.

In general, `Rate()` may have zero or multiple solutions. The implementation uses an interactive search algorithm. The optional `guess` may be provided as a starting point for the search, which will usually result in the solution closest to `guess` being returned. If no solution is found in 30 iterations, `Rate()` returns `NaN`.
Example  You obtain a 30-year mortgage at a supposed 7% annual percentage rate for $100K. To do so, you pay $2,000 up front in “points”, and another $1,500 in fees. Assuming you hold the loan for its full term, the effective interest rate of your loan (for you) is
\[
\text{Rate}(30, \text{Pmt}(7\%, 30, 100K), 100K-3500) \rightarrow 7.36\%
\]

\textbf{Xirr(values, dates, i, guess)}

Returns the annual internal rate of return (IRR) for a series of payments (negative values) and inflows (positive values) that occur at non-periodic intervals. Both \texttt{values} and \texttt{dates} must be indexed by \texttt{i}. The \texttt{values} array constrains the cash flow amounts, the \texttt{dates} array contains the date of each payment or inflow, where each date is Analytica’s expressed as the number of days since Jan. 1, 1904. The rate is based on a 365 day year.

If the cash flow never changes sign, there is no solution and \texttt{Xirr()} returns \texttt{NaN}. If the cash flow changes sign more than once, \texttt{Xirr()} may have multiple solutions, but will return only the first solution found. The optional parameter, \texttt{guess}, may be provided as a starting point for the iterative search, and \texttt{Xirr()} will generally find the solution closest to \texttt{guess}. If not provided, \texttt{guess} defaults to 10%. If no solution is found within 30 iterations, \texttt{Xirr()} returns \texttt{NaN}.

To compute the IRR for a series of period payments, use \texttt{Irr()}.

\begin{example}
\texttt{EarningAmt: J}
\begin{tabular}{|c|c|c|c|}
\hline
1 & 2 & 3 & 4 \\
\hline
-400K & -200K & 100K & 600K \\
\hline
\end{tabular}
\end{example}

\texttt{EarningDate: J}
\begin{tabular}{|c|c|c|c|}
\hline
1 & 2 & 3 & 4 \\
\hline
July 5, 1999 & Dec 1, 1999 & Jan 21, 2000 & Aug 10, 2001 \\
\hline
\end{tabular}

\texttt{XIrr(EarningAmt,EarningDate,J) \rightarrow 9.31\%}

\textbf{Tip} \texttt{EarningDate} can be entered by selecting \texttt{Number Format} from the \texttt{Result} menu while editing the table for \texttt{EarningDate}. From the \texttt{Number format} dialog, select a date format, then enter the dates.

\textbf{Xnpv(rate, values, dates, i)}

Returns the net present value (NPV) of a non-periodic cash flow with a constant discount rate. \texttt{rate} is the annual discount rate for a 365 day year. Both \texttt{values}, the cash-flow amounts, and \texttt{dates}, the date of each payment (negative value) or inflow (positive value), must be indexed by \texttt{i}.

See also \texttt{Npv()}.

\begin{example}
Using the cash flow shown in the example for \texttt{Xirr()} above, the net present value at a 5% discount rate is:
\[
\text{XNpv}(5\%, \text{EarningAmt, EarningDate, J}) \rightarrow \$42,838.71
\]
\end{example}
Financial library functions

The following functions are not built-in to Analytica, but are located in the Financial library that comes with Analytica.

**Calloption (S, X, T, r, theta)**

This function calculates the value of a call option using the Black-Scholes formula. For further information on the Black-Scholes model for option pricing see *Basic Black-Scholes: Option Pricing and Trading* by Timothy Falcon Crack.

**Parameters**
- \( S \) = price of security now
- \( X \) = exercise price
- \( T \) = time in years to exercise
- \( r \) = risk-free interest rate
- \( \theta \) = volatility of security

**Library** Financial (add-in library)

**Example**

```plaintext
Calloption(50, 50, 0.25, 0.05, 0.3) → 3.292
```

**Syntax**

```
Calloption (S, X, T, r, theta:Numeric)
```

**Putoption (S,X,T,r,theta)**

This function calculates the value of a put option using the Black-Scholes formula. For further information on the Black-Scholes model for option pricing see *Basic Black-Scholes: Option Pricing and Trading* by Timothy Falcon Crack.

**Parameters**
- \( S \) = price of security now
- \( X \) = exercise price
- \( T \) = time in years to exercise
- \( r \) = risk-free interest rate
- \( \theta \) = volatility of security

**Library** Financial (add-in library)

**Example**

```plaintext
Putoption(50, 50, 0.25, 0.05, 0.3) → 2.67
```

**Syntax**

```
Putoption (S, X, T, r, theta:Numeric)
```

**Capm (Rf,Rm,Beta)**

**Parameters**
- \( R_f \) = risk free rate
- \( R_m \) = market return
\textbf{Beta} = beta of individual stock. Beta is the relative marginal contribution of the stock to the market return, defined as the ratio of the covariance between the stock return and market return, to the variance in the market return.

**Library** Financial (add-in library)

**Example** \( \text{Capm}(8\%, 12\%, 1.5) \rightarrow 0.14 \)

**Syntax** \( \text{Capm}(Rf, Rm, \text{Beta:Numeric}) \)

\textbf{CostCapme (rOpp, rD, Tc, L)}

This function calculates Miles and Ezzell's (M/E) formula for adjusting the weighted average cost of capital for financial leverage. The M/E formula works when the firm adjusts its future borrowing to keep debt proportions constant.

**Parameters**
- \( r\text{Opp} \) = opportunity cost of capital
- \( rD \) = expected return on debt
- \( Tc \) = net tax saving per dollar of interest paid. This is difficult to pin down in practice and is usually taken as the corporate tax rate.
- \( L \) = debt-to-value ratio

**Library** Financial (add-in library)

**Example** \( \text{CostCapme}(14\%, 8\%, 35\%, 0.5) \rightarrow 0.1252 \)

**Syntax** \( \text{CostCapme}(r\text{Opp}, rD, Tc, L: \text{Numeric}) \)

\textbf{CostCapmm (rAllEq, Tc, L)}

This function calculates Modigliani and Miller's (M/M) formula for adjusting the weighted average cost of capital for financial leverage. The M/M formula works for any project that is expected to

1. Generate a level, perpetual cash flow.
2. Support fixed permanent debt.

**Parameters**
- \( r\text{AllEq} \) = cost of capital under all-equity financing
- \( Tc \) = net tax saving per dollar of interest paid. This is difficult to pin down in practice and is usually taken as the corporate tax rate.
- \( L \) = debt-to-value ratio

**Library** Financial (add-in library)

**Example** \( \text{CostCapmm}(20\%, 35\%, 0.4) \rightarrow 0.172 \)

**Syntax** \( \text{CostCapmm}(r\text{AllEq}, Tc, L: \text{Numeric}) \)

\textbf{Implied_volatility_c (S, X, T, r, p)}

This function calculates the implied volatility of a call option, based on using the Black-Scholes formula for options.

**Parameters**
- \( S \) = price of security now
Chapter 13 Other Functions

Financial library functions

- X = exercise price
- T = time in years to exercise
- r = risk-free interest rate
- p = option price

Library Financial (add-in library)

Example Implied_volatility_c(50, 35, 4, 6%, 15) → 3.052e-005

Syntax Implied_volatility_c (S,X,T,r,p : atomic numeric)

Implied_volatility_p (S,X,T,r,p)

This function calculates the implied volatility of a put option, based on using the Black-Scholes formula for options.

Parameters
- S = price of security now
- X = exercise price
- T = time in years to exercise
- r = risk-free interest rate
- p = option price

Library Financial (add-in library)

Example Implied_volatility_p(50, 35, 4, 6%, 15) → 9.416e-001

Syntax Implied_volatility_p (S,X,T,r,p : atomic numeric)

Pvperp (C, rate)

Pvperp() calculates the present value of a perpetuity (a bond that pays a constant amount in perpetuity).

Parameters
- C = constant payment amount
- rate = interest rate per period

Library Financial (add-in library)

Example Pvperp(200,8%) → 2500

Syntax Pvperp(C, rate: Numeric)

Pvgperp (C1, rate, growth)

Pvgperp() calculates the present value of a growing perpetuity (a bond that pays an amount growing at a constant rate in perpetuity).

Parameters
- C1 = payment amount in year 1
- rate = interest rate per period
- growth = growth rate per period

Library Financial (add-in library)
Example: \( \text{PVGPerp}(200, 8\%, 6\%) \rightarrow 10K \)

Syntax: \( \text{PVGPerp}(C1, \text{rate}, \text{growth} : \text{Numeric}) \)

**Wacc (Debt,Equity,rD,rE,Tc)**

\( \text{Wacc()} \) calculates the after-tax weighted average cost of capital, based on the expected return on a portfolio of all the firm's securities. Used as a hurdle rate for capital investment.

**Parameters**
- **Debt** = market value of debt
- **Equity** = market value of equity
- **rD** = expected return on debt
- **rE** = expected return on equity
- **Tc** = corporate tax rate

**Library** Financial (add-in library)

**Example**
\( \text{Wacc}(1M, 3M, 8\%, 16\%, 35\%) \rightarrow 0.133 \)

Syntax: \( \text{Wacc}(\text{Debt},\text{Equity},\text{rD},\text{rE},\text{Tc} : \text{Numeric}) \)

---

### Advanced probability functions

The following functions are not actual probability distributions, but they are useful for various probabilistic analyses, including building other probability distributions. You can find them in the Advanced math library from the Definition menu.

**BetaFn(a, b)** The beta function, defined as:

\[
\text{BetaFn}(a, b) = \int_0^1 x^{a-1} (1-x)^{b-1} \, dx
\]

**BetaI(x, a, b)** The incomplete beta function, defined as:

\[
\text{BetaI}(x, a, b) = \frac{1}{\text{Beta}(a, b)} \int_0^x x^{a-1} (1-x)^{b-1} \, dx
\]

The incomplete beta function is equal to the cumulative probability of the beta distribution at \( x \). It is useful in a number of mathematical and statistical applications.

The cumulative binomial distribution, defined as the probability that an event with probability \( p \) occurs \( k \) or more times in \( n \) trials, is given by:

\[
Pr = \text{BetaI}(p, k, n-k+1)
\]
The student’s distribution with \( n \) degrees of freedom, used to test whether two observed distributions have the same mean, is readily available from the beta distribution as:

\[
\text{Student}(x|n) = 1 - \text{BetaI}(n/(n + x^2), n/2, 1/2)
\]

The F-distribution, used to test whether two observed samples with \( n_1 \) and \( n_2 \) degrees of freedom have the same variance, is readily obtained from \( \text{BetaI} \) as:

\[
F(x, n_1, n_2) = \text{BetaI}(n_2/(n_1x + n_2))
\]

**Combinations(k, n)**  
"n choose k." The number of unique ways that \( k \) items can be chosen from a set of \( n \) elements (without replacement and ignoring the order).

\[
\text{Combinations}(2, 4) \rightarrow 6
\]

They are: \{1,2\}, \{1,3\}, \{1,4\}, \{2,3\}, \{2,4\}, \{3,4\}

**Permutations(k, n)**  
The number of possible permutations of \( k \) items taken from a bucket of \( n \) items.

\[
\text{Permutations}(2, 4) \rightarrow 12
\]

They are: \{1,2\}, \{1,3\}, \{1,4\}, \{2,1\}, \{2,3\}, \{2,4\}, \{3,1\}, \{3,2\}, \{3,4\}, \{4,1\}, \{4,2\}, \{4,3\}

**CumNormal(x, mean, stddev)**  
Returns the cumulative probability:

\[
p = \Pr[x \leq X]
\]

for a normal distribution with a given mean and standard deviation. \text{mean} and \text{stddev} are optional and default to \text{mean} = 0, \text{stddev} = 1.

\[
\text{CumNormal}(1) - \text{CumNormal}(-1) \rightarrow .683
\]

That is, 68.3% of the area under a normal distribution is contained within one standard deviation of the mean.

**CumNormalInv(p, m, s)**  
The inverse cumulative probability function for a normal distribution with mean \( m \) and standard deviation \( s \). Returns the value \( X \) where:

\[
p = \Pr[x \leq X]
\]

\text{mean} and \text{stddev} are optional and default to \text{mean} = 0, \text{stddev} = 1.

**Erf(x)**  
The error function, defined as:

\[
\text{Erf}(x) = \frac{2}{\sqrt{\pi}} \int_0^x e^{-t^2} dt
\]

**ErfInv(y)**  
The inverse error function. Returns the value \( X \) such that \( \text{Erf}(X) = y \).

\[
\text{ErfInv}(\text{Erf}(2)) \rightarrow 2
\]

**GammaFn(x)**  
Returns the gamma function of \( x \), defined as:

\[
\Gamma(x) = \int_0^\infty t^{x-1} e^{-t} dt
\]

The gamma function grows very quickly. For example, when \( n \) is an integer, \( \text{GammaFn}(n+1) = n! \). For this reason, it is often preferable to use the \text{LGamma()} function.

**Gammal(x, a, b)**  
Returns the incomplete gamma function, defined as:
The incomplete gamma function returns the cumulative area from zero to \( x \) under the gamma distribution.

The incomplete gamma function is useful in a number of mathematical and statistical contexts.

The cumulative Poisson distribution function, which encodes the probability that the number of Poisson random events (\( x \)) occurring will be less than \( k \) (where \( k \) is an integer) where the expected mean number is \( a \), is given by (recall that parameter \( b \) is optional):

\[
P(x < k) = \Gamma(a, k)
\]

\textbf{Gammall\( \text{Inv}(y, a, b) \)} The inverse of the incomplete gamma function. Returns the value \( X \) such that \( \Gamma(X, a, b) = y \). \( b \) is optional and defaults to 1.
This chapter shows you how to:

- Choose a distribution
- Define a variable as a distribution
- Use Analytica’s built-in probability distributions
Analytica makes it easy to model and analyze uncertainties even if you have minimal background in probability and statistics. The graphs below review several key concepts from probability and statistics that will help you understand the probabilistic modeling facilities in Analytica. This chapter assumes that you have encountered most of these concepts before, but possibly in the distant past. If you need more information, see “Glossary” on page 421 or refer to an introductory text on probability and statistics.

Choosing an appropriate distribution

With Analytica you can express uncertainty about any variable by using a probability distribution. You may base the distribution on available relevant data, on the judgment of a knowledgeable individual, or on some combination of data and judgment.

Answer the following questions about the uncertain quantity to select the most appropriate kind of distribution:

- Is it discrete or continuous?
- If continuous, is it bounded?
- Does it have one mode or more than one?
- Is it symmetric or skewed?
- Should you use a standard or a custom distribution?

We will discuss how to answer each of these in turn.
Chapter 14

Expressing Uncertainty

Choosing an appropriate distribution

Is the quantity discrete or continuous?

When trying to express uncertainty about a quantity, the first technical question is whether the quantity is discrete or continuous.

A discrete quantity has a finite number of possible values — for example, the gender of a person or the country of a person’s birth. Logical or Boolean variables are a type of discrete variable with only two values, true or false, sometimes coded as yes or no, present or absent, or 1 or 0 — for example, whether a person was born before January 1, 1950, or whether a person has ever resided in California.

A continuous quantity can be represented by a real number, and has infinitely many possible values between any two values in its domain. Examples are the quantity of an air pollutant released during a given period of time, the distance in miles of a residence from a source of air pollution, and the volume of air breathed by a specified individual during one year.

For a large discrete quantity, such as the number of humans residing within 50 miles of Disneyland on December 25, 1980, it is often convenient to treat it as continuous. Even though you know that the number of live people must be an integer, you may want to represent uncertainty about the number with a continuous probability distribution.

Conversely, it is often convenient to treat continuous quantities as discrete by partitioning the set of possible values into a small finite set of partitions. For example, instead of modeling human age by a continuous quantity between 0 and 120, it is often convenient to partition people into infants (age < 2 years), children (3 to 12), teenagers (13 to 19), young adults (20 to 40), middle-aged (41 to 65), and seniors (over 65 years). This process is termed discretizing. It is often convenient to discretize continuous quantities before assessing probability distributions.

Does the quantity have bounds?

If the quantity is continuous, it is useful to know if it is bounded before choosing a distribution — that is, does it have a minimum and/or maximum value?

Some continuous quantities have exact lower bounds. For example, a river flow cannot be less than zero (assuming the river cannot reverse direction). Some quantities also have exact upper bounds. For example, the percentage of a population that is exposed to an air pollutant cannot be greater than 100%.

Most real world quantities have de facto bounds — that is, you can comfortably assert that there is zero probability that the quantity would be smaller than some lower bound, or larger than some upper bound, even though there is no precise way to determine the bound. For example, you can be sure that no human could weigh more than 5000 pounds; you might be less sure whether 500 pounds is an absolute upper bound.

Many standard continuous probability distributions, such as the normal distribution, are unbounded. In other words, there is some probability that a normally distributed quantity
Choosing an appropriate distribution

How many modes does it have?

The mode of a distribution is its most probable value. The mode of an uncertain quantity is the value at the highest peak of the density function, or, equivalently, at the steepest slope on the cumulative probability distribution.

![Mode](image)

Important questions to ask about a distribution are how many modes it has, and approximately where it, or they, are? Most distributions have a single mode, but some have several and are known as multimodal distributions.

If a quantity has two or more modes, you can usually view it as a combination of two or more populations. For example, the distribution of ages in a daycare center at leaving time might include one mode at age 3 for the children and another mode at age 27 for the parents and caretakers. There is obviously a population of children and a population of parents. It is generally easier to decompose a multimodal quantity into its separate components and assess them separately than to assess a multimodal distribution. You can then assess a unimodal (single mode) probability distribution for each component, and combine them to get the aggregate distribution. This approach is often more convenient, because it lets you assess single-mode distributions, which are easier to understand and evaluate than multimodal distributions.

![Modes](image)

Is the quantity symmetric or skewed?

A symmetrical distribution is symmetrical about its mean. A skewed distribution is asymmetric. A positively skewed distribution has a thicker upper tail than lower tail; and vice versa, for a negatively skewed distribution.

![Symmetry](image)

Probability distributions in environmental risk analysis are often positively skewed. Quantities such as source terms, transfer factors, and dose-response factors, are typically bounded below by zero. There is more uncertainty about how large they might be than about how small they might be.

![Skew](image)

A standard or custom distribution?

The next question is whether to use a standard parametric distribution — for example, normal, lognormal, or beta — or a custom distribution, where the assessor specifies points on the cumulative probability or density function.

![Distribution](image)
Considering the physical processes that generate the uncertainty in the quantity may suggest that a particular standard distribution is appropriate. More often, however, there is no obvious standard distribution to apply.

It is generally much faster to assess a standard distribution than a full custom distribution, because standard distributions have fewer parameters, typically from two to four. You should usually start by assigning a simple standard distribution to each uncertain quantity using a quick judgment based on a brief perusal of the literature or telephone conversation with a knowledgeable person. You should assess a custom distribution only for those few uncertain inputs that turn out to be critical to the results. Therefore, it is important to be able to select an appropriate standard distribution quickly for each quantity.

### Defining a variable as a distribution

To define a variable as an Analytica probability distribution, first select the variable and open either the variable’s **Object** window or the **Attribute** panel of the diagram (see “The Attribute panel” on page 23) with **Definition** selected from the **Attribute** popup menu (see “Creating or editing a definition” on page 116).

To define the distribution:

1. Click the **Expression** popup menu above the definition field and select **Distribution**.

   ![Expression popup menu](image)

   The **Object Finder** opens, showing the Distribution library.
Defining a variable as a distribution

2. Select the distribution you wish to use.

3. Enter the values for the parameters. You can use an expression or refer to other variables by name in the parameter fields.

4. Click OK to accept the distribution.

If the parameters of the distribution are single numbers, a button appears with the name of the distribution, indicating that the variable is defined as a distribution. To edit the parameters, click this button.

Alternatively, you can directly enter a distribution as an expression:

1. Set the cursor in the definition field and type in the distribution name and parameters, for example:
   \[ \text{Normal}(0.105,0.015) \]

2. Press Alt-Enter or click the \( \checkmark \) button.

You can also paste a distribution from the Distribution library in the Definition menu (see “Using a library” on page 346).

You can edit a distribution as an expression, whether it was entered as a distribution from the Distribution library or as an expression, by selecting expr from the Expression popup menu.
Chapter 14  
Expressing Uncertainty

Including a distribution in a definition

You can enter a distribution anywhere in a definition, including in a cell of an edit table. Thus, you can have arrays of distributions.

To enter a distribution:

1. Set the insertion point where you wish to enter the distribution in the definition field or edit table cell.
2. Enter the distribution in any of the following ways:
   • Type in the name of the distribution.
   • Paste it from the Distribution library under the Definition menu.
   • Select Paste Identifier from the Definition menu to paste it from the Object Finder.
3. Type in missing parameters, or replace parameters enclosed as <<x>>.

Probabilistic calculation

Analytica performs probabilistic evaluation of probability distributions through simulation — by computing a random sample of values from the actual probability distribution for each uncertain quantity. The result of evaluating a distribution is represented internally as an array of the sample values, indexed by Run. Run is an index variable that identifies each sample iteration by an integer from 1 to Samplesize.

You can display a probabilistic value using a variety of uncertainty view options — the mean, statistics, probability bands, probability density (or mass function), and cumulative distribution function (see “Uncertainty views” on page 32). All these views are derived or estimated from the underlying sample array, which you can inspect using the last uncertainty view, Sample.

Example  A: Normal(10, 2) →

<table>
<thead>
<tr>
<th>Iteration (Run)</th>
<th>1</th>
<th>2</th>
<th>3</th>
<th>4</th>
<th>5</th>
<th>6</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>10.74</td>
<td>13.2</td>
<td>9.092</td>
<td>11.44</td>
<td>9.519</td>
<td>13.03</td>
</tr>
</tbody>
</table>
Chapter 14  Expressing Uncertainty

Tip

The values in a sample are generated at random from the distribution; if you try this example and display the result as a table, you may see values different from those shown here. To reproduce this example, reset the random number seed to 99 and use the default sampling method and random number method (see “Uncertainty Setup dialog box” on page 232).

For each sample run, a random value is generated from each probability distribution in the model. Output variables of uncertain variables are calculated by calculating a value for each value of Run.

Example

B: Normal(5, 1) →

<table>
<thead>
<tr>
<th>Iteration (Run)</th>
<th>1</th>
<th>2</th>
<th>3</th>
<th>4</th>
<th>5</th>
<th>6</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>5.09</td>
<td>4.94</td>
<td>4.65</td>
<td>6.60</td>
<td>5.24</td>
<td>6.96</td>
</tr>
</tbody>
</table>

C: A + B →

<table>
<thead>
<tr>
<th>Iteration (Run)</th>
<th>1</th>
<th>2</th>
<th>3</th>
<th>4</th>
<th>5</th>
<th>6</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>15.83</td>
<td>18.13</td>
<td>13.75</td>
<td>18.04</td>
<td>14.76</td>
<td>19.99</td>
</tr>
</tbody>
</table>

Notice that each sample value of C is equal to the sum of the corresponding values of A and B.

To control the probabilistic simulation, as well as views of probabilistic results, use the Uncertainty Setup dialog box (see “Uncertainty Setup dialog box” on page 232).

Tip

If you try to apply an array reducing function (see “Array-reducing functions”) to a probability distribution across Run, Analytica returns the distribution’s mid value.

Example:

X: Beta(2, 3)

Mid(X) → 0.3857 and Max(X, Run) → 0.3857

To evaluate the input parameters probabilistically and reduce across Run, use Sample() (see page 280).

Example:

Max(Sample(X), Run) → 0.8892

Uncertainty Setup dialog box

Use the Uncertainty Setup dialog box to inspect and change the sample size, sampling method, statistics, probability bands, and samples per plot point for probability distributions. All settings are saved with your model.

To open the Uncertainty Setup dialog box, select Uncertainty Options from the Result menu or Control+u. To set values for a specific variable, select the variable before opening the dialog box.

The five options for viewing and changing information in the Uncertainty Setup dialog box can be accessed using the Analysis option popup menu.
Chapter 14  Expressing Uncertainty

Uncertainty Setup dialog box

Uncertainty sample  To change the sample size or sampling method for the model, select the **Uncertainty Sample** option from the **Analysis option** popup menu.

The default dialog box shows only a field for sample size. To view and change the sampling method, random number method, or random seed, press the **More Options** button.

Sample size  This number specifies how many runs or iterations Analytica performs to estimate probability distributions. Larger sample sizes take more time and memory to compute, and produce smoother distributions and more precise statistics. See “Selecting the Sample Size” for guidelines on selecting a sample size. The sample size must be between 2 and 32,000. You can access this number in expressions in your models as the system variable **Samplesize**.

Sampling method  The sampling method is used to determine how to generate a random sample of the specified sample size, \( m \), for each uncertain quantity, \( x \). Analytica provides three options:
• **Simple Monte Carlo**

The simplest sampling method is known as Monte Carlo, named after the randomness prevalent in games of chance, such as at the famous casino in Monte Carlo. In this method, each of the \( m \) sample points for each uncertainty quantity, \( x \), is generated at random from \( x \) with probability proportional to the probability density (or probability mass for discrete quantities) for \( x \). Analytica uses the inverse cumulative method; it generates \( m \) uniform random values, \( u_i \), for \( i = 1, 2, \ldots, m \), between 0 and 1, using the specified random number method (see below). It then uses the inverse of the cumulative probability distribution to generate the corresponding values of \( x \).

\[
X_i \text{ where } P(x \leq X_i) = u_i \text{ for } i = 1, 2, \ldots, m.
\]

With the simple Monte Carlo method, each value of every random variable \( x \) in the model, including those computed from other random quantities, is a sample of \( m \) independent random values from the true probability distribution for \( x \). You can therefore use standard statistical methods to estimate the accuracy of statistics, such as the estimated mean or fractiles of the distribution, as for example described in “Selecting the Sample Size”.

• **Median Latin hypercube (the default method)**

With median Latin hypercube sampling, Analytica divides each uncertain quantity \( x \) into \( m \) equiprobable intervals, where \( m \) is the sample size. The sample points are the medians of the \( m \) intervals, that is, the fractiles

\[
X_i \text{ where } P(x \leq X_i) = (i-0.5)/m \text{ for } i = 1, 2, \ldots, m.
\]

These points are then randomly shuffled so that they are no longer in ascending order, to avoid nonrandom correlations among different quantities.

• **Random Latin hypercube**

The random Latin hypercube method is similar to the median Latin hypercube method, except that instead of using the median of each of the \( m \) equiprobable intervals, Analytica samples at random from each interval. With random Latin hypercube sampling, each sample is a true random sample from the distribution. However, the samples are not totally independent.

Choosing a sampling method

The advantage of Latin hypercube methods is that they provide more even distributions of samples for each distribution than simple Monte Carlo sampling. Median Latin hypercube is still more evenly distributed than random Latin hypercube. If you display the PDF of a variable that is defined as a single continuous distribution, or is dependent on a single continuous uncertain variable, using median Latin hypercube sampling, the distribution will usually look fairly smooth even with a small sample size (such as 20), whereas the result using simple Monte Carlo will look quite noisy.

If the variable depends on two or more uncertain quantities, the relative noise-reduction of Latin hypercube methods is reduced. If the result depends on many uncertain quantities, the performance of the Latin hypercube methods may not be discernibly better than simple Monte Carlo. Since the median Latin hypercube method is sometimes much better, and almost never worse than the others, Analytica uses it as the default method.

Very rarely, median Latin hypercube can produce incorrect results, specifically when the model has a periodic function with a period similar to the size of the equiprobable intervals. For example, with

\( X: \text{Uniform}(1, \text{Samplesize}) \)
Y: \( \sin(2\pi x) \)

median Latin hypercube method will give very poor results. In such cases, you should use random Latin hypercube or simple Monte Carlo. If your model has no periodic function of this kind, you do not need to worry about the reliability of median Latin hypercube sampling.

To change the probability bands displayed when you select **Probability Bands** as the uncertainty view for a result, select the **Probability Bands** option from the **Analysis option** popup menu.

**Probability density and cumulative probability options**
To change how probability density or the cumulative probability values are drawn or to change their resolution, select the respective option from the **Analysis option** popup menu.
Analytica estimates the probability density function and cumulative distribution function, like other uncertainty views, from the underlying array of sample values for each uncertain quantity. As with any simulation-based method, each estimated distribution will have some noise and variability from one evaluation to the next.

**Samples per plot point**

This number controls the average number of sample values used to estimate each point on the probability density function (PDF) or cumulative distribution function (CDF) curves.

For a small number of samples per plot point (less than or equal to 10), more points are each estimated from fewer sample values and so are more susceptible to random noise. If the quantity is defined by a single probability distribution, and if you use median Latin hypercube method (the default), this noise will be slight and the curve will look smooth. In other cases, the noise may have a large effect, and using a larger number of samples per plot point will produce a smoother curve. There is a trade-off; with larger numbers the smoothing may miss details of the shape of the curve. PDFs may be much more susceptible to random noise than CDFs, so you may wish to use larger numbers for PDFs than CDFs. Ultimately, to reduce the noise, use a larger sample size (for details on selecting the sample size, see “Selecting the Sample Size” on page 398).

**Equal probability steps**

With this option, Analytica uses the sample to estimate a set of \( m+1 \) fractiles (quantiles), \( x_p \), at equal probability intervals, where \( p = 0, q, 2q, \dots, 1 \), and \( q = \frac{1}{m} \). The cumulative probability is plotted at each of the points \( x_p \), increasing in equal steps along the vertical axis. Points are plotted closer together along the horizontal axis in the regions where the density is the greatest. In the probability density graph view, the areas under the density function between successive fractiles are equal because they each represent the same probability, \( q \). The density between two successive fractiles is plotted at the midpoint (on the horizontal axis) of the two fractiles.

**Equal X axis steps**

With this option, Analytica estimates cumulative probability using equally spaced points along the \( x \) axis. In the probability density graph view, it shows a histogram where the height of each horizontal is estimated as the fraction of the sample values that fall within that \( x \) interval.
Chapter 15

Probability Distributions

This chapter describes how to define uncertain quantities using probability distributions, discrete or continuous. You can use standard parametric distributions, such as a Normal, Uniform, Bernoulli, or binomial, or custom distributions, where you specify points in tables or arrays. You can also create multivariate distributions over an array of uncertain quantities.
Probability distributions

The built-in Distribution library (available from the Definition menu) offers a wide range of distributions for discrete and continuous variables. (See “Is the quantity discrete or continuous?” and “Glossary” on page 421 for an explanation of this distinction.) Some are standard or parametric distributions with just a few parameters, such as Normal and Uniform, which are continuous, and Bernoulli and Binomial, which are discrete. Others are custom distributions, such as CumDist, which lets you specify an array of points on a cumulative probability distribution, and Probtable (page 248), which lets you edit a table of probabilities for a discrete variable conditional on other discrete variables.

There are a variety of ways to create arrays of uncertain quantities, or multivariate distributions (see “Multivariate distributions”). You may set parameters to array values, specify an index to the optional Over parameter, or use functions from the Multivariate library.

Parametric discrete distributions

Bernoulli \( (p) \)

Defines a discrete probability distribution with probability \( p \) of result 1 and probability \( 1 - p \) of result 0. It generates a sample containing 0s and 1s, with the proportion of 1s is approximately \( p \). \( p \) is a probability between 0 and 1, inclusive, or an array of such probabilities. The Bernoulli distribution is equivalent to:

\[
\text{If Uniform}(0, 1) < p \text{ Then 1 Else 0}
\]

Library Distribution

Example

The domain, List of numbers, is \([0, 1]\).

\( \text{Bernoulli}\_\text{ex}: \text{Bernoulli} (0.3) \rightarrow \)

Binomial\( (n, p) \)

An event that can be true or false in each trial, such as a coin coming down heads or tails on each toss, with probability \( p \) has a Bernoulli distribution. A binomial distribution describes the number of times an event is true, e.g., the coin is heads in \( n \) independent trials or tosses where the event occurs with probability \( p \) on each trial.

The relationship between the Bernoulli and binomial distributions means that an equivalent, if less efficient, way to define a Binomial distribution function would be:

\[
\text{Function Binomial2}(n, p) \\
\text{Parameters: } (n: \text{Atom}; p) \\
\text{Definition: Index } i := 1..n; \\
\quad \text{Sum}(\text{FOR } J := I \text{ DO Bernoulli}(p), i)
\]
The parameter $n$ is qualified as an Atom to ensure that the sequence $1..n$ is a valid one-dimensional index value. It allows Binomial2 to array abstract if its parameters $n$ or $p$ are arrays.

### Poisson($m$)

*Poisson process* generates random independent events with a uniform distribution over time and a mean of $m$ events per unit time. Poisson($m$) generates the distribution of the number of events that occur in one unit of time. You might use the Poisson distribution to model the number of sales per month of a low-volume product, or the number of airplane crashes per year.

### Geometric($p$)

The geometric distribution describes the number of independent Bernoulli trials until the first successful outcome occurs, for example, the number of coin tosses until the first heads. The parameter $p$ is the probability of success on any given trial.

### Hypergeometric($s$, $m$, $n$)

The hypergeometric distribution describes the number of times an event occurs in a fixed number of trials without replacement, e.g., the number of red balls in a sample of $s$ balls drawn without replacement from an urn containing $n$ balls of which $m$ are red. Thus, the parameters are:

- $s$: The sample size, e.g., the number of balls drawn from an urn without replacement. Cannot be larger than $n$.
- $m$: The total number of successful events in the population, e.g., the number of red balls in the urn.
- $n$: The population size, e.g., the total number of balls in the urn, red and non-red.

### Uniform( min, max, Integer:True )

The Uniform distribution with the optional integer parameter set to True returns discrete distribution over the integers with all integers between and including $min$ and $max$ having equal probability.

Uniform(5,14,Integer:True) →
Probability density and mass graphs

When you select the **Probability density** as the Uncertainty view (see “Uncertainty views” on page 32) for a *continuous* variable, it graphs the distribution as a **Probability Density function**. The height of the density shows the relative likelihood the variable will have that value:

Technically, the probability density of variable $x$, means the probability per unit increment of $x$. The units of probability density are the reciprocal of the units of $x$ — if the units of $x$ are dollars, the units of probability density are probability per dollar increment.

If you select **Probability density** as the Uncertainty view for a *discrete* variable, it actually graphs the **Probability Mass** function — using a bar graph style to display the probability of each discrete value as the height of each bar:
Similarly, if you choose the **cumulative probability** Uncertainty view for a *discrete* variable, it actually displays the **cumulative probability mass** distribution as a bar graph. Each bar shows the cumulative probability that $X$ will have that value or any lower value:

---

**Is a distribution discrete or continuous?**

Almost always, Analytica can figure out whether a variable is discrete or continuous, and so choose the probability density or probability mass view as appropriate — so you don’t need to worry about it. If the values are text, it knows it must be discrete. If the numbers are integers, such as generated by Bernoulli, Poisson, binomial, and other discrete parametric distributions, it also assumes it is discrete.

Infrequently, a discrete distribution may contain numbers that are not integers, which it may not recognize as discrete, for example,

$$\text{Chance Indiscrete} := \text{Poisson}(4) \times 0.5$$

In this case, you can make sure it does what you want by specifying the domain attribute of the variable as discrete (or continuous). The next section on the domain attribute explains how.
Chapter 15 Probability Distributions

The domain attribute and discrete variables

The **domain** attribute specifies the set of possible values for a variable. You rarely need to view or change a domain attribute explicitly. The most common reason to set the domain is for a variable defined as a custom discrete distribution, especially **ProbTable**. You can do this by editing it directly as an index in the probtable view (see “Probtable(): Probability Tables”), so you can usually ignore the information below. The rare case you will need it is to specify a distribution as discrete, when Analytica would not otherwise figure it out — because it has non-integer numerical value.

By default, the domain type is **Automatic**, meaning Analytica figures it out when it needs to. Usually, this is obvious (see previous section). For a discrete quantity, the domain may be a **list of numbers** or a **list of labels**. If the domain is **continuous**, it means that any number is valid.

**Editing the domain**

You can view and edit the domain like any other attribute of a variable, in the **Attribute** panel:

1. Select the variable.
2. Open the **Attribute** panel, and select **Domain** from the **Attribute** menu.
3. Select the domain type from the popup menu:

   - **Automatic**: The default, meaning Analytica should figure it out.
   - **Continuous**: Any number. All other types are discrete.
   - **Discrete Numeric** and **Categorical**: Discrete but its values are unspecified.
   - **List of Numbers**: You specify a list of numbers.
   - **List of Labels**: You specify a list of label (text) values, as illustrated.
   - **Index**: You enter the name of an index variable, to use its values as the domain, or another variable to copy its domain values.

4. If you choose **List of Numbers** or **List of Labels**, you enter the list values in the usual way (see ).
Custom discrete probabilities

These functions let you specify a discrete probability distribution using a custom set of values, text (label) values, or numbers.

Protable(): Probability Tables

To describe a probability distribution on a discrete variable whose domain is a list of numbers or list of labels, you use special kind of edit table called a probability table (or probtable) (see “Arrays and Indexes” on page 151).

Create a probability table

To define a variable using a probability table:

1. Determine the variable’s domain — number or labels for its possible values.
2. Select the variable and view its definition attribute in the Object window or Attribute panel of the Diagram window (see “The Attribute panel” on page 23).
3. Press the Expression menu above the definition field and select Probability Table.

Tip

The domain of a discrete variable should include all its possible values. If not, its probability mass function may sum to less than 1.
If the variable already has a definition, it confirms that you wish to replace it.

**Tip** If the definition of a variable is already a probability table, a **ProbTable** button appears in the definition. Click it to open the **Edit Table** window (see “Viewing an array as an edit table” on page 155).

4. The **Indexes** dialog opens to confirm your choices for the indexes of the table. It already includes the selected variable (self) among the selected indexes. Other options are variables with a domain that is a list of numbers or list of labels. Add or remove any other variables that you want to condition this variable on.

**Tip** **Self** is required as an index of a probability table. It refers to the domain (possible values) of this variable.

5. Click the **OK** button. An **Edit Table** window appears.

6. Enter the possible values for the domain in the left column. As in any edit table, press **Enter** or down-arrow in the last row to add a row. Select **Insert row** (**Control+i**) or **Delete row** (**Control+k**) from the **Edit** menu. If they are numbers, they must be in increasing order.

7. Enter the probability of each possible outcome in the second column. The probabilities should sum to 1. You may enter literal numbers or expressions.

**Example** If **p** is a variable whose value is a probability (between 0 and 1) and the possible weather outcomes are sunny and rainy, you might define a probability table for weather thus:
Expression view of probability table

The Weather probability table when viewed as an expression, looks like this:

\[ \text{Probtable}(\text{Self}) (p, (1-p)) \]

The domain values do not appear in the expression view, and it is not very convenient for defining a probability table. More generally, the expression view of a multidimensional probability table looks like this:

\[ \text{Probtable}(i_1, i_2, \ldots, \text{in}) (p_1, p_2, p_3, \ldots, p_m) \]

This example is an n-dimensional conditional probability table, indexed by the indexes \( i_1, i_2, \ldots, \text{in} \). One index must be \( \text{Self} \). \( p_1, p_2, p_3, \ldots, p_m \) are the probabilities in the array. \( m \) is the product of the sizes of the indexes \( i_1, i_2, \ldots, \text{in} \).

Add a conditioning variable

You may wish to add one or more conditioning variables to a probability table, to create conditional dependency. Each discrete conditioning variable adds a dimension to the table. For example, in the Weather probability table (see page 247), the probability of rain may depend on the season. So you might have \( \text{Season} \) as a conditioning variable, defined as a list of labels:

\[ \text{Variable} \ \text{Season} := \{ \text{‘Winter’}, \text{‘Spring’}, \text{‘Summer’}, \text{‘Fall’} \} \]

1. Open the Edit Table window by clicking the ProbTable button.
2. Click the indexes button to open the Indexes dialog box.
3. Click the All Variables check box above the left hand list.
4. Move the desired variable, e.g., \( \text{Season} \), to add it as an index.
5. Click the OK button to accept the changes.

The resulting table is indexed by both the domain of your variable and the domains of the conditionally dependent variables. You need to enter a probability for each cell. The probabilities must sum to one over the domain of the variable (sunny and rainy in the example), not over the conditioning index(es).

Tip

You must have already specified the variables as probability tables, before adding them with the Indexes dialog box.

Determtable(): Deterministic conditional table

Determtable() defines the value of a variable as a deterministic (not uncertain) function of one or more discrete variables. It gives a value conditional on the value of one or more discrete variables, often including a probabilistic discrete variable and a discrete decision variable defined as a list. We include it in this section on discrete probability distributions, even though it is not probabilistic, because you will usually use it in con-
Creating a determtable

To define a variable as a determtable:

1. Determine the variable’s domain — the list of possible outcomes.
2. Press the Expression popup menu above the definition field and select Other.

Analytica opens the Object Finder dialog box (see “Object Finder dialog” on page 121).

3. Select Array from the Library popup menu and select Determtable from the function list:

4. Click the Indexes button to open the Indexes dialog, which lets you choose discrete conditioning variables:
5. Click **OK** to accept the indexes and open an **Edit Table** window.

6. Enter the outcomes corresponding to each outcome of your discrete inputs.

**Expression view of a determtable**

When you select the expression view of a definition that was created as a determtable, it looks like this: You cannot initially create a determtable as an expression.

\[
\text{Determinable}(i_1, i_2, \ldots i_n)(r_1, r_2, r_3, \ldots r_m)
\]

This describes an \(n\)-dimensional conditional deterministic table, indexed by the indexes \(i_1, i_2, \ldots i_n\). The last index, \(i_n\), is the innermost index, varying the most rapidly. \(r_1, r_2, \ldots r_m\) are the outcomes in the array.

**Example**

In “Create a probability table”, **Weather** is defined as a probability table. If \(P\), the probability of “sunny”, is 0.4, then the probability of “rainy” is 0.6. **Party_location** is a decision variable with values [‘outdoors’, ‘porch’, ‘indoors’]. **value_to_me** is a determtable, containing utility values (or "payoffs") for each combination of **Party_location** and **Weather**:

Evaluating **value_to_me** gives the value of each party location, considering the uncertain distribution of **Weather**. The mean value of **value_to_me** is the expected utility.
Chancedist (p, a, i)

Creates a discrete probability distribution, where \(a\) is an array of outcome values, numbers or text, and \(p\) is the corresponding array of probabilities. \(a\) and \(p\) must both be indexed by \(i\). The values of \(a\) must be unique; if \(a\) is numeric the values must be increasing.

**When to use**

Use Chancedist() instead of ProbTable() when:

- The array of outcome \(a\) is multidimensional, or
- You want to use other variables or expressions to define the outcomes or probability arrays.

**Library**

Distribution

**Example**

\[
\begin{array}{|c|c|c|}
\hline
\text{Index}_b & \text{Red} & \text{White} & \text{Blue} \\
\hline
\text{Array}_q \\
\text{Index}_b & \text{Red} & \text{White} & \text{Blue} \\
\hline
0.3 & 0.2 & 0.5 \\
\hline
\end{array}
\]

The domain of the variable is a list of labels: ['Red', 'White', 'Blue'].

\[
\text{Chancedist}(\text{Array}_q, \text{Index}_b, \text{Index}_b) \rightarrow
\]
Parametric continuous distributions

**Tip** To produce the example graphs of distributions below, we used a sample size of 1000, equal sample probability steps, samples per PDF of 10, and we set the graph style to line. Even if you use the same options, your graphs may look slightly different due to random variation in the Monte Carlo sampling.

**Uniform(min, max)**

Creates a uniform distribution between values min and max. If omitted, they default to 0 and 1. If you specify optional parameter Integer: True, it returns a discrete distribution consisting of only the integers between min and max, each with equal probability. See “Uniform( min, max, Integer:True )”.

**When to use** If you know nothing about the uncertain quantity other than its bounds, a uniform distribution between the bounds is appealing. However, situations in which this is truly appropriate are rare. Usually, you know that one end or the middle of the range is more likely than the rest — that is, the quantity has a mode. In such cases, a beta or triangular distribution is a better choice.

**Library** Distribution

**Example** Uniform(5, 10) →
Chapter 15  Probability Distributions

Parametric continuous distributions

Triangular(min, mode, max)

Creates a triangular distribution, with minimum \( \text{min} \), most likely value \( \text{mode} \), and maximum \( \text{max} \). \( \text{min} \) must not be greater than \( \text{mode} \), and \( \text{mode} \) must not be greater than \( \text{max} \).

When to use
Use the triangular distribution when you have the bounds and the mode, but have little other information about the uncertain quantity.

Library
Distribution

Example
\[ \text{Triangular}(2, 7, 10) \rightarrow \]
Normal(mean, stddev)

Creates a normal or Gaussian probability distribution with mean and standard deviation stddev. The standard deviation must be 0 or greater. The range [mean - stddev, mean + stddev] encloses about 68% of the probability.

When to use
Use a normal distribution if the uncertain quantity is unimodal and symmetric and the upper and lower bounds are unknown, possibly very large or very small (unbounded). This distribution is particularly appropriate if you believe that the uncertain quantity is the sum or average of a large number of independent, random quantities.

Library
Distribution

Example
Normal(30, 5) →

Lognormal(median, gsdev, mean, stddev)

Creates a lognormal distribution. You can specify its median and geometric standard deviation gsdev, or its mean and standard deviation stddev, or any two of these four parameters. The geometric standard deviation, gsdev, must be 1 or greater. It is sometimes also known as the uncertainty factor or error factor. The range [median/gsdev, median x gsdev] encloses about 68% of the probability — just like the range [mean - stddev, mean + stddev] for a normal distribution with standard deviation stddev.

median and gsdev must be positive.

If x is lognormal Ln(x) has a normal distribution with mean Ln(median) and standard deviation Ln(gsdev).

When to use
Use the lognormal distribution if you have a sharp lower bound of zero but no sharp upper bound, a single mode, and a positive skew. The gamma distribution is also an option in this case. The lognormal is particularly appropriate if you believe that the uncertain quantity is the product (or ratio) of a large number of independent random variables. The multiplicative version of the central limit theorem says that the product or ratio of many independent variables tends to lognormal — just as their sum tends to a normal distribution.
Beta \((x, y, \min, \max)\)

Creates a beta distribution of numbers between 0 and 1 if you omit optional parameters \(\min\) and \(\max\). \(x\) and \(y\) must be positive. If you specify \(\min\) and/or \(\max\), it shifts and expands the beta distribution to so that they form the lower and upper bounds. The mean is:

\[
\frac{x}{x + y} \times (\max - \min) + \min
\]

When to use

Use a beta distribution to represent uncertainty about a continuous quantity bounded by 0 and 1 (0% or 100%) with a single mode. It is particularly useful for modeling an opinion about the fraction (percentage) of a population that has some characteristic. For example, suppose you are trying to estimate the long run frequency of heads, \(h\), for a bent coin about which you know nothing. You could represent your prior opinion about \(h\) as a uniform distribution,

\[
\text{Uniform}(0, 1)
\]

or equivalently,

\[
\text{Beta}(1, 1)
\]

If you observe \(r\) heads in \(n\) tosses of the coin, your new (posterior) opinion about \(h\) should be:

\[
\text{Beta}(1 + r, 1 + n - r)
\]

If the uncertain quantity has lower and upper bounds other than 0 and 1, include the lower and upper bounds parameters to obtain a transformed beta distribution. The transformed beta is a very flexible distribution for representing a wide variety of bounded quantities.
Beta (5, 10) →

Exponential(r)

Describes the distribution of times between successive independent events in a Poisson process with an average rate of r events per unit time. The rate r is the reciprocal of the mean of the Poisson distribution — the average number of events per unit time. Its standard deviation is also 1/r.
A model with exponentially distributed times between events is said to be Markov, implying that knowledge about when the next event occurs does not depend on the system's history or how much time has elapsed since the previous event. More general distributions such as the gamma or Weibull do not exhibit this property.

**Gamma(a, b)**

Creates a gamma distribution with shape parameter \(a\) and scale parameter \(b\). The scale parameter, \(b\), is optional and defaults to \(b=1\). The gamma distribution is bounded below by zero (all sample points are positive) and is unbounded from above. It has a theoretical mean of \(a \cdot b\) and a theoretical variance of \(a \cdot b^2\). When \(a > b\), the distribution is unimodal with the mode at \((a - 1) \cdot b\). An exponential distribution results when \(a = 1\). As \(a \to \infty\), the gamma distribution approaches a normal distribution in shape.

The gamma distribution encodes the time required for \(a\) events to occur in a Poisson process with mean arrival time of \(b\).

**Tip** Some textbooks use Rate=1/\(b\), instead of \(b\), as the scale parameter.

**When to use** Use the gamma distribution with \(a>1\) if you have a sharp lower bound of zero but no sharp upper bound, a single mode, and a positive skew. The Lognormal distribution is also an option in this case. **Gamma()** is especially appropriate when encoding arrival times for sets of events. A gamma distribution with a large value for \(a\) is also useful when you wish to use a bell-shaped curve for a positive-only quantity.

**Library** Distribution

**Examples** Gamma distributions with mean=1:
Logistic(m, s)

The logistic distribution describes a distribution with a cumulative density given by:

\[ F(x) = \frac{1}{1 + e^{-(x-m)/s}} \]

The distribution is symmetric and unimodal with tails that are heavier than the normal distribution. It has a mean and mode of \( m \), variance of:

\[ \frac{\pi^2 \times s^2}{3} \]

and kurtosis of 6/5 and no skew. The scale parameter, \( s \), is optional and defaults to 1.

The logistic distribution is particularly convenient for determining dependent probabilities using linear regression techniques, where the probability of a binomial event depends monotonically on a continuous variable \( x \). For example, in a toxicology assay, \( x \) may be the dosage of a toxin, and \( p(x) \) the probability of death for an animal exposed to that dosage. Using \( p(x) = F(x) \), the logit of \( p \), given by

\[ \text{Logit}(p(x)) = \ln\left( \frac{p(x)}{1-p(x)} \right) = \frac{x}{s} - \frac{m}{s} \]

has a simple linear form. This linear form lends itself to linear regression techniques for estimating the distribution — for example, from clinical trial data.

Example: Logistic(10, 10)

StudentT(d)

The StudentT describes the distribution of the deviation of a sample mean from the true mean when the samples are generated by a normally distributed process centered on the true mean. The \( T \) statistic is:

\[ T = (m - x) / (s \sqrt{n}) \]
where $x$ is the sample mean, $m$ is the actual mean, $s$ is the sample standard deviation, and $n$ is the sample size. $T$ is distributed according to StudentT with $d = n - 1$ degrees of freedom.

The StudentT distribution is often used to test the statistical hypothesis that a sample mean is significantly different from zero. If $x_1..x_n$ measurements are taken to test the hypothesis $m > 0$,

$$\text{GetFract(StudentT(n-1), 0.95)}$$

is the acceptance threshold for the $T$ statistic. If $T$ is greater than this fractile, we can reject the null hypothesis (that $m <= 0$) at 95% confidence. When using GetFract for hypothesis testing, be sure to use a large sample size, since the precision of this computation improves with sample size.

The StudentT can also be useful for modeling the power of hypothetical experiments as a function of the sample size $n$, without having to model the outcomes of individual trials.

Samples from the StudentT distribution are generated using the Monte Carlo sampling method only, regardless of the uncertainty settings. Latin Hypercube methods for sample generation are not available.

**Example**  

```plaintext
StudentT(8)
```

The Weibull distribution has a cumulative density given by:

$$f(x) = 1 - e^{-\left(\frac{x}{s}\right)^n}$$

for $x >= 0$. It is similar in shape to the gamma distribution, but tends to be less skewed and tail-heavy. It is often used to represent failure time in reliability models. In such models, $f(x)$ may represent the proportion of devices that experience a failure within
the first $x$ time units of operation, the number of insurance policy holders that file a claim within $x$ days.

Example: $\text{Weibull}(10, 4) \rightarrow$

![ChiSquared(d) distribution](image)

ChiSquared(d)

The ChiSquared() distribution with $d$ degrees of freedom describes the distribution of a Chi-Squared metric defined as:

$$\chi^2 = \sum_{i=1}^{n} y_i^2$$

where each $y_i$ is independently sampled from a standard normal distribution and $d = n - 1$. The distribution is defined over non-negative values.

The Chi-squared distribution is commonly used for analyses of second moments, such as analyses of variance and contingency table analyses. It can also be used to generate the F distribution. Suppose

Variable $V := \text{ChiSquared}(k)$
Variable $W := \text{ChiSquared}(m)$
Variable $S := (V/k) \times (W/m)$

$s$ is distributed as an $F$ distribution with $k$ and $m$ degrees of freedom. The $F$ distribution is useful for the analysis of ratios of variance, such as a one-factor between-subjects analysis of variance.
Custom continuous distributions

These functions let you specify a continuous probability distribution by specifying any number of points on its cumulative or density function.

Cumdist(p, r, i)

Specifies a continuous probability distribution as an array of cumulative probabilities, \( p \), and an array of corresponding outcome values, \( r \). The values of \( p \) must be non-decreasing, start with 0, and end with 1. The values of \( r \) must be increasing. Either \( r \) must be an index of \( p \), in which case you can omit \( i \), or \( p \) and \( r \) must both be indexed by \( i \). If \( p \) or \( r \) have more than one index, you must specify the common index \( i \) to link \( p \) and \( r \).

By default, it fits the cumulative distribution using piecewise cubic monotonic interpolation between the specified points, so that the PDF is also continuous. If you set the optional parameter Smooth to False, it uses piecewise linear interpolation for the CDF, so that the PDF is piecewise uniform.

Library Distribution

Example

\[
\begin{array}{ccc}
1 & 2 & 3 \\
0 & 0.6 & 1.0
\end{array}
\]

\[
\begin{array}{ccc}
1 & 2 & 3 \\
10 & 20 & 30
\end{array}
\]

\[
\text{CumDist(Array_b, Array_x)} \rightarrow
\]

![Graph of Cumdist function Example]
Custom continuous distributions

**Probdist**(p, r, i)

Specifies a continuous probability distribution as an array of probability densities, p, for an array of corresponding values, r. The values of r must be increasing. The probability densities p must be non-negative. It normalizes the densities so that the total probability integrates to 1.

Usually the first and last values of p should be 0. If not, it assumes zero at 2r₁ - r, (or 2rₙ - rₙ₋₁).

Either r must be an index of p, or p and r must have an index in common. If p or r have more than one index, you must specify the index i to link p and r.

It produces the density function using linear interpolation between the points on the density function (quadratic on CDF).

Probdist(Array_p, Array_r) →
Special probabilistic functions

Certain(u)

Returns the mid (deterministic) value of \( u \) even if \( u \) is uncertain and evaluated in a prob (probabilistic) context. It is not strictly a probability distribution. It is sometimes useful in browse mode, when you want to replace an existing probability distribution defined for an input (see “Using input nodes”) with a non-probabilistic value.

Library Distribution

Shuffle(a , i)

Shuffle returns a random reordering (permutation) of the values in array \( a \) over index \( i \). If you omit \( i \), it evaluates \( a \) in prob mode, and shuffles the resulting sample over Run. You can use it to generate an independent random sample from an existing probability distribution \( a \).

If \( a \) contains dimensions other than \( i \), it shuffles each slice over those other dimensions independently over \( i \). If you want to shuffle the slices of a multidimensional array over index \( i \), without shuffling the values within each slice, use this method:

\[
A[@I = \text{Shuffle}(@I, I)]
\]

This shuffles \( A \) over index \( I \), without shuffling each slice over its other indexes.

Truncate(u, min, max)

Truncates an uncertain quantity \( u \) so that it has no values below \( \text{min} \) or above \( \text{max} \). You must specify one or both \( \text{min} \) and \( \text{max} \).

It does not discard sample values below \( \text{min} \) or above \( \text{max} \): It generates a new sample that has approximately same probability distribution as \( u \) between \( \text{min} \) and \( \text{max} \), and no values outside them. The values of the result sample have the same rank order as the input \( u \), so the result retains the same rank-correlation that \( u \) had with any predecessor.

It gives an error if \( u \) is not uncertain, or if \( \text{min} \) is greater than \( \text{max} \). It gives a warning if no sample values of \( u \) are in the range \( \text{min} \) to \( \text{max} \). In mid mode, it returns an estimate of the median of the truncated distribution. Unlike other distribution functions, even in mid mode, it evaluates its parameter \( u \) (and therefore any of its predecessors) in prob mode. It always evaluates \( \text{min} \) and \( \text{max} \) in mid mode.

Examples We define a normal distribution, \( X \), and variables \( A \), \( B \), and \( C \) that truncate \( X \) below, above, and on both sides. Then we define a variable to compare \( A \), \( B \), and \( C \) and display its result in the probability density view:

\[
\begin{align*}
\text{Chance } X & := \text{Normal}(10, 2) \\
\text{Chance } A & := \text{Truncate}(X, 7) \\
\text{Chance } B & := \text{Truncate}(X, , 10) \\
\text{Chance } C & := \text{Truncate}(X, 8, 12) \\
\text{Variable Compare_truncated_x} & := [A, B, C]
\end{align*}
\]
Chapter 15  Probability Distributions

Special probabilistic functions

Library  Distribution

Random(expr)

Generates a single value randomly sampled from expr, which, if given, must be a call to a probability distribution with all needed parameters, for example:

Random(Uniform(-100,100))

returns a single real-valued random number uniformly selected between -100 and 100. If you omit parameter expr, it generates one sample from the uniform distribution 0 to 1, for example:

Random( Uniform(-100,100) ) → 74.4213148
Random( ) → 0.265569265

Random is not a true distribution function, since it generates only a single value from the distribution, whether in mid or prob context. It generates each single sample using Monte Carlo, not Latin hypercube sampling, no matter what the global setting in the uncertainty setup. It is often useful when you need a random number generator stream, such as for rejection sampling, Metropolis-Hastings simulation, and so on.

Random has these parameters, all optional:

Parameters  dist: If specified, must be a call to a distribution function that supports single-sample generation (see below). Defaults to Uniform(0,1).

Method: Selects the random number generator: 0=default, 1=Minimal standard, 2=L'Ecuyer, 3=Knuth.

Over: A convenient way to list index(es) so that the result is an array of independent random numbers with this index or indexes. For example:

Random(Over: I)

returns an array of independent uniform random numbers between 0 and 1 indexed by I. It is equivalent to:
Random supports all built-in probability distribution functions with the exception of Fractiles, ProbDist, and Truncate. It supports Bernoulli, Beta, Binomial, Certain, ChiSquared, CumDist, Exponential, Gamma, Geometric, HyperGeometric, Logistic, LogNormal, Normal, Poisson, StudentT, Triangular, Uniform, Weibull. It supports these distributions in the Distribution Variations library: Beta_m_sd, Chancedist, Erlang, Gamma_m_sd, InverseGaussian, Lorenzian, NegBinomial, Pareto, Pert, Rayleigh, Smooth_Fractile, and Wald, and these distributions from the Multivariate Distributions library: BiNormal, Dirichlet, Dist_additive_growth, Dist_compound_growth, Dist_serial_correl, Gaussian, Multinomial, MultiNormal, MultiUniform, Normal_additive_gro, Normal_compound_gro, Normal_correl, Normal_serial_correl, UniformSpherical, Wishart, and InvertedWishart.

User-defined functions can be used as a parameter to Random, if they are given an optional parameter declared as:

```
singleSampleMethod: Optional Atom Number
```

If the parameter is provided, the distribution function must return a single random variate from the distribution indicated by the other parameters. The value specifies the random number generator to use: 0=default, 1=Minimal standard, 2=L'Ecuyer, 3=Knuth.

## Multivariate distributions

A multivariate distribution is a distribution over an array of quantities — or, equivalently, an array of distributions. Analytica's Intelligent Array features make it relatively easy to generate multivariate distributions. There are three main ways: To create an array of identical independent distributions, use the Over parameter. To create an array of independent distributions with different parameters, pass array(s) of parameter values to the function. To create an array of dependent distributions, use a function from the Multivariate Distributions library, which lets you specify a dependence as a correlation, correlation matrix, or covariance matrix. See the following sections for details.

### Over indexes as parameters to probability distributions

If you want to generate an array of identical, independent distributions, the simplest method is to specify the index(es) in the `Over` parameter, for example:

```
Normal(10, 2, Over: K)
```

generates an array of independent normal distributions, each with mean 10 and standard deviation 2, over index K. All parametric distributions accept `Over:` as an optional parameter. `Over:` allows multiple indexes if you want to create a multidimensional array of identically distributed quantities. For example, this will generate a three-dimensional array of independent, identically distributed uniform distributions:

```
Uniform(0, 10, Over: I, J, K)
```

### Probability distributions with array parameters

Probability distribution functions fully support Intelligent Arrays. If a parameter is an array, the function will generate an array of independent distributions over any index(es) of the array. For example,
Index K := ['A', 'B', 'C']
Variable Xmean := Table(K)(10, 11, 12)
Variable X := Normal(Xmean, 2)

X will be an array of normal distributions over index K, each with the corresponding
mean. If you define a normal distribution with two parameters (mean and standard devi-
ation) with the same Index(es) — in this case, Xmean and Ysd are both indexed by k:

Variable Ysd := Table(K)(2, 3, 4)
Variable Y := Normal(Xmean, Ysdeviation)

it generates an array of normal distributions over index K, each with corresponding
mean and standard deviation. More generally, the result is an array with the union of the
indexes of all its parameters — just the same as all other functions and operations that
support Intelligent Arrays.

The custom probability distributions, including ProbTable, ProbDist, and CumDist,
expect their parameters to be arrays of probabilities, probability densities, or values,
with a common index. In this case, the common index is used in generating the random
sample and does not appear in the result. But, if those array parameters have any other
indexes, those indexes will also appear in the result, following the usual rules of Intelli-
gent Arrays.

Multivariate Distribution library

This library offers a variety of functions for generating probability distributions that are
dependent or correlated. It is distributed with Analytica. To add this library to your model
see “Adding library to a model” on page 331.

Many of these functions specify dependence among distributions using a rank correla-
tion number or matrix, also known as the Spearman correlation. Unlike the Pearson or
product-moment correlation, rank correlation is a non-parametric measure of correla-
tion. It is equivalent to the Pearson correlation on the ranks of the same. It does not
assume that the relationship is linear, and applies to ordinal as well as interval-scale
variables. It is therefore a more robust statistic. For example, it is a more stable way to
estimate the relationship between two random samples when one or both has a long tail
— such as a lognormal distribution. In such cases, Pearson correlation may be misleadingly
large (or small) when an extreme sample in the tail of one sample does (or does
not) correspond with an extreme value in the other sample.

The methods provided to generate general multivariate distributions with specified rank
correlation, first generate multivariate normal (Gaussian) distributions with specified
rank correlation, and then transform them to the desired marginal distributions. The
rank correlations are not changed by such transformation.

The method for generating the correlated distribution (based on Iman & Conover) works
for median and random Latin Hypercube as well as simple Monte Carlo simulation
methods. The rank-correlations of the results are approximately, but not exactly, equal
to the specified rank-correlations. The accuracy of the approximation increases with the
sample size.
Create one distribution dependent on another

*Normal_correl(m, s, r, y)*

Generates a normal distribution with mean \( m \), standard deviation \( s \), and correlation \( r \) with uncertain quantity \( y \). In mid mode, it returns \( m \). If \( y \) is not normally distributed, the result will also not be normal, and the correlation will be approximate. It generalizes appropriately if any of the parameters are arrays. The result array will have the union of the indexes of the parameters.

*Correlate_with(s, ref, rc)*

Reorders the samples of \( s \) so that the result has the identical values to \( s \), and a rank correlation close to \( rc \) with the reference sample, \( ref \).

Example: To generate a lognormal distribution with a 0.8 rank correlation with \( Z \), use:

\[
\text{Correlate_with(LogNormal(2, 3), Z, 0.8)}
\]

*Note:* If you have a non-default SampleWeighting of points, the weighted rank correlation may differ from \( rc \).

*Dist_reshape(x, newdist)*

Reshapes the probability distribution of uncertain quantity \( x \), so that it has the same marginal probability distribution (i.e., same set of sample values) as \( newdist \), but retains the same ranks as \( x \) over \( \text{Run} \). Thus:

\[
\text{Rank(Sample(x), Run)} = \text{Rank(Sample(Dist_reshape(x, y)), Run)}
\]

In a Mid context, it simply returns \( \text{Mid(newdist)} \), with any indexes of \( x \).

The result retains any rank correlations that \( x \) may have with other predecessor variables. So, the rank-order correlation between a third variable \( z \) and \( x \) is the same as the rank-order correlation between \( z \) and a reshaped version of \( x \), like this:

\[
\text{RankCorrel(x, z)} = \text{RankCorrel(Dist_reshape(x, y), z)}
\]

The operation may optionally be applied along an index \( r \) other than \( \text{Run} \).

An array of distributions with correlation or covariance matrix

*Correlate_dists(x, rcm, m, i, j)*

Given an array \( x \) indexed by \( i \) of uncertain quantities, it reorders the samples so as to match the desired rank correlation matrix, \( rcm \) between the \( x[i] \) as closely as possible. \( rcm \) is indexed by \( i \) and \( j \), which must be the same length. It must be positive definite, and the diagonal should be all ones. The result has the same marginal distributions as \( x[i] \), and rank correlations close to those specified in \( rcm \). In mid mode, it returns \( \text{Mid(x)} \).
Gaussian(m, cvm, i, j)

Generates a multivariate Gaussian (i.e., normal) distribution with mean vector, \( m \), and covariance matrix, \( cvm \). \( m \) is indexed by \( i \). \( cvm \) must be a symmetric and positive-definite matrix, indexed by \( i \) and \( j \), which must be the same length. It is similar to Multinormal() except that it takes a covariance matrix instead of a rank correlation matrix.

Multinormal(m, s, cm, i, j)

Generates a multivariate normal (or Gaussian) distribution with mean \( m \), standard deviation \( s \), and correlation matrix \( cm \). \( m \) and \( s \) may be scalar or indexed by \( i \). \( cm \) must be a symmetric, positive-definite matrix, indexed by \( i \) and \( j \), which must be the same length. It is similar to Gaussian, except that it takes a correlation matrix instead of a covariance matrix.

BiNormal(m, s, i, c)

A 2-D Normal (or bivariate Gaussian) distribution with means \( m \), standard deviations \( s \) (>0) and correlation \( c \) between the two variables. The index \( i \) must have exactly two elements. \( s \) must be indexed by \( i \).

Other parametric multivariate distributions

Dirichlet(alpha, i)

A Dirichlet distribution with parameters \( alpha > 0 \) indexed by \( i \). Each sample of a Dirichlet distribution produces a random vector indexed by \( i \) whose elements sum to 1. It is commonly used to represent second order probability information.

The Dirichlet distribution has a density given by:

\[
k \ast \text{Product}(x^{(alpha-1)}, i)
\]

where \( k \) is a normalization factor equal to:

\[
\text{GammaFn}(\text{Sum(alpha, i)})/\text{Sum(GammaFn(alpha), i)}
\]

The \( alpha \) parameters can be interpreted as observation counts. The mean is given by the relative values of \( alpha \) (normalized to 1), but the variance narrows as the alphas get larger, just as your confidence in a distribution would narrow as you get more samples.

The Dirichlet lends itself to easy Bayesian updating, if you have a prior of \( alpha = 0 \), and you have \( N \) observations.

Multinomial(n, theta, i)

Returns the multinomial distribution, a generalization of the binomial distribution to \( n \) possible outcomes. For example, if you were to roll a fair die \( n \) times, the outcome would be the number of times each of the six numbers appears. \( theta \) would be the probability of each outcome, where \( \text{Sum(theta, i)} = 1 \), and index \( i \) is the list of possible outcomes. If \( theta \) doesn’t sum to 1, it is normalized.

Each sample is a vector indexed by \( i \) indicating the number of times the corresponding outcome (die number) occurred during that sample point. Each sample has the property

\[
\text{Sum(result, I )} = n
\]
UniformSpherical(i, r)

Generates points uniformly on a sphere (or circle or hypersphere). Each sample generated is indexed by i, so if i has three elements, the points lie on a sphere.

The mid value is a bit strange here since there isn’t really a median that lies on the sphere. Obviously the center of the sphere is the middle value, but that isn’t in the allowed range. So, it returns an arbitrary point on the sphere.

MultiUniform(cm, i, j, lb, ub)

The multi-variate uniform distribution.

Generates vector samples (indexed by i) such that each component has a uniform marginal distribution, and each component has the pair-wise correlation matrix cm, indexed by i and j, which must have the same number of elements. cm needs to be symmetric and must obey a certain semidefinite condition, namely that the transformed matrix \[ 2^\sin(30^\circ \text{cov}) \] is positive semidefinite. (In most cases, this roughly the same as cm being positive semidefinite.) lb and ub can be used to specify upper and lower bounds, either for all components, or individually if these bounds are indexed by i. If lb and ub are omitted, each component has marginal Uniform(0, 1).

Note: cm is the true sample correlation, not rank correlation.

The transformation is based on:

Arrays with serial correlation

These six functions each generate an array of distributions over an index t such that each distribution has a specified serial correlation with the preceding element over t. They are especially useful for modeling dynamic processes or Markov processes over time, where the value at each time step depends probabilistically on the value at the preceding time. Normal_serial_corr() and Dist_serial_corr() generate arrays of serially correlated distributions that are normal and arbitrary, respectively. Normal_additive_gro() and Dist_additive_growth() produce arrays with uncertain additive growth with serial correlation. Normal_compound_gro() and Dist_compound_growth() produce arrays with uncertain compound growth with serial correlation.

Normal_serial_corr(m, s, r, t)

Generates an array of normal distributions over index t with mean m, standard deviation s, and serial correlation r between successive values over index t. You can give each distribution a different mean and/or standard deviation if m and/or s are arrays indexed by t. If r is indexed by t, \( r[t=k] \) specifies the correlation between \( \text{result}[t=k] \) and \( \text{result}[t=k-1] \). (Then it ignores the first correlation, \( r[@t=1] \).)

Dist_serial_corr(x, r, t)

Generates an array y over time index t where each \( y[t] \) has a marginal distribution identical to x, and serial rank correlation of rc with \( y[t-1] \). If x is indexed by t, each \( y[t] \) has
the same marginal distribution as $x[t]$, but with samples reordered to have the specified rank correlation $r$ between successive values. If $r$ is indexed by $t$, $r[@t=k]$ specifies the rank correlation between $y[@t=k]$ and $y[@t=k-1]$. Then the first correlation, $r[@t=1]$, is ignored.

**Normal_additive_gro(x, m, s, r, t)**

Generates an array of values over index $t$, with the first equal to $x$, and successive values adding an uncertain growth, normally distributed with mean $m$ and standard deviation $s$. If we denote the result by $g$, $r$ specifies a serial correlation between $g[@t=k]$ and $g[@t=k-1]$. $x$, $m$, $s$, and $r$ each may be indexed by $t$ if you want them to vary over $t$.

**Dist_additive_growth(x, g, rc, t)**

Generates an array of values over index $t$, with the first equal to $x$, and successive values adding an uncertain growth $g$, and serial correlation $rc$ between $g[@t=k]$ and $g[@t=k-1]$. $x$, $g$, and $rc$ each may be indexed by $t$ if you want them to vary over $t$.

**Normal_compound_gro(x, m, s, r, t)**

Generates an array of values over index $t$, with the first equal to $x$, and successive values multiplied by compound growth $1+g$, where $g$ is normally distributed with mean $m$ and standard deviation $s$. It applies serial correlation $r$ between $g[@t=k]$ and $g[@t=k-1]$. $x$, $g$, and $rc$ each may be indexed by $t$ if you want them to vary over $t$.

**Dist_compound_growth(x, g, rc, t)**

Generates an array of values over index $t$, with the first equal to $x$, and successive values multiplying by an uncertain compound growth $g$, and serial rank correlation $rc$ between $g[@t=k]$ and $g[@t=k-1]$. $x$, $g$, and $rc$ each may be indexed by $t$ if you want them to vary over $t$.

**Uncertainty over regression coefficients**

For a description of `RegressionDist()`, `RegressionNoise()`, and `RegressionFitProb()`, see “Uncertainty in regression results”.

**Importance weighting**

**Importance weighting** is a powerful enhancement to Monte Carlo and Latin hypercube simulation that lets you get more useful information from fewer samples; it is especially valuable for risky situations with a small probability of an extremely good or bad outcome. By default, all simulation samples are equally likely. With importance weighting, you set `SampleWeighting` to generate more samples in the most important areas. Thus, you can get more detail where it matters and less where it matters less. Results showing probability distributions with uncertainty views and statistical functions reweight sample values using `SampleWeighting` so that the results are unbiased.

You can also modify `SampleWeighting` interactively to reflect different input distributions and so rapidly see the effects the effects on results without having to rerun the
importance weighting

To set up importance weighting, you set weights to each sample point in the built-in variable `SampleWeighting`. Here is how to open its Object window:

1. De-select all nodes, e.g., by clicking in the background of the diagram.
2. From the Definition menu, select System Variables, and then SampleWeighting. Its Object window opens:

Initially, its definition is 1, meaning it has an equal weight of 1 for every sample. (1 is equivalent to an array of 1s, e.g., `Array(Run, 1)`). For importance weighting, you assign a different weighting array indexed by `Run`. It automatically normalizes the weighting to sum to one, so you need only supply relative weights.

Suppose you have a distribution on variable \( X \), with density function \( f(x) \), which has a small critical region in \( cr(x) \) — in which \( x \) causes a large loss or gain. To generate the distribution on \( x \), we use a mixture of \( f(x) \) and \( cr(x) \) with probability \( p \) for \( cr(x) \) and \( (1-p) \) for \( f(x) \). Then use the sampleWeighting function to adjust the results back to what they should be is:

\[
\frac{f(x)}{((p f(x) + (1 - p) cr(x))}
\]

For example, suppose you are selecting the design Capacity in Megawatts for an electrical power generation system for a critical facility to meet an uncertain Demand in Megawatts which has a lognormal distribution:

\[
\begin{align*}
\text{Chance Demand} & := \text{Lognormal}(100, 1.5) \\
\text{Decision Capacity} & := 240 \\
\text{Probability(Demand)} & \rightarrow 0.015
\end{align*}
\]

In other words, the probability of failing to meet demand is about 1.5%, according to the probabilistic simulation of the lognormal distribution. Suppose the operator receives Price of 20 dollars per Megawatt-hour delivered, but must pay Penalty of 200 dollars per megawatt-hour of demand that it fails to supply to its customers:

\[
\begin{align*}
\text{Variable Price} & := 100 \\
\text{Variable Penalty} & := 1000
\end{align*}
\]
Variable Revenue := IF Demand <= Capacity THEN Price*Demand
ELSE Price*Capacity - (Demand - Capacity)*Penalty

Mean (Revenue) → $2309

The estimated mean revenue of $2309 is imprecise because there is a small (1.5%) probability of a large penalty ($200 per Mwh that it cannot supply), and only a few sample points will be in this region. You can use Importance sampling to increase the number of samples in the critical region, where Demand > Capacity.

Chance Excess_demand := Truncate(Demand, 150)
Variable Mix_prob := 0.6
Variable Weighted_demand := If Bernoulli(Mix_prob)
THEN Excess_demand ELSE Demand

SampleWeighting := Density(Demand) / 
((1 - Mix_prob)*Density(Demand) + 
Mix_prob*Density(Excess_demand))

Thus, we compute a Weighted_demand as a mixture between the original distribution on Demand and the distribution in the critical region, Excess_demand. We assign weights to SampleWeighting, using the Object window for SampleWeighting opened as described above. See the Analytica Wiki at http://www.lumina.com/wiki for more.

For more on weighted statistics and conditional statistics, see “Weighted statistics and w parameter”.

This chapter describes:

- Statistical functions that compute statistics, such as mean, variance, or correlation over a probabilistic value (or for arrays with other indexes).
- Tornado charts and importance analysis to see how to apportion credit or blame for the uncertainty in an output to its uncertain inputs.
- XY plots and scatter plots to visualize the effect of an input on an output.
- Functions that show the sensitivity of a variable to one or more variables that affect it, including WhatIf and Tornado analysis.
- Functions to perform regression analysis.
Statistical functions

Statistical functions compute a statistic from a probability distribution. More precisely, they estimate the statistic from a random sample of values representing a probabilistic value. Common examples are Mean, Variance, Correlation, and Getfract (which returns a fractile or percentile). The uncertainty view options available in the Result window (see “Uncertainty views”) use these functions.

Unlike other functions, statistical function usually force their main parameter(s) to be evaluated in prob mode (probabilistically) and they return a nonprobabilistic value — whether they are evaluated in a mid mode or prob mode. For example:

```
Chance X := Normal(0, 1)
Variable X90 := Getfract(X, .9)
X90 → 1.259
```

Evaluating variable X90 causes variable X to be evaluated in prob mode, so that Getfract(X, 90%) can estimate the 90th percentile (0.9 fractile) of the distribution for X. X90 itself has only a mid value, and no probabilistic value. The exception is the Mid(x) function that forces x to be evaluated in mid mode, no matter the evaluation context.

The default usage of statistical functions is over a probability distribution, represented as a random sample indexed by Run. You can also use these functions to compute statistics over an array with a different index by specifying that index explicitly. This is often useful for computing statistics from data tables — including if you want to fit a probability distribution to a set of data. For example, suppose Data is an array of imported measurements:

```
Index K := 1..1000
Variable Data:= Table(K)(123.4, 252.9, 221.4, ...)
Variable Xfitted := Normal(Mean(Data,K), Sdeviation(Data,K)
```

Xfitted is a normal distribution fitted to Data with the same mean and standard deviation.

Tip
All statistical functions produce estimates from the underlying random sample for each probabilistic quantity. These estimates are not exact, but will vary from one evaluation to the next due to the variability inherent in random sampling. Hence, your results may not exactly match the results shown in the examples here. For greater precision, use a larger sample size (see “Selecting the Sample Size” on how to select a sample size).

Notation in formulas
The formulas used to define statistics use this notation:

- $x_i$: the $i$th sample value of probabilistic variable $x$
- $\bar{x}$: the mean of probabilistic variable $x$ (see Mean())
- $s$: standard deviation (see Sdeviation())
- $m$: sample size (see Appendix A, “Selecting the Sample Size”).

Statistics and text-valued distributions
Most statistical functions require their parameters to be numerical. A few statistical functions, those that only requiring ordinal (ordered) values, also work on distributions with text values (whose domain is a list of labels), namely: Frequency (use Frequency(X, x)), Mid, Min, Max, Probability_bands, and Sample. These functions assume the values are ordered as specified in the domain list of labels, e.g. Low, Mid, High.
Example model

The examples in this section use the following variables:

- Variable Alt_fuel_price := Normal(1.25, 0.1)
- Variable Fuel_price := Normal(1.19, 0.1)
- Variable Skfuel_price := Beta(4, 2, 1, 1.5)

Mean(x)

Returns an estimate of the mean of x if x is probabilistic. Otherwise, returns x.

\[
\text{Mean}(x) = \frac{1}{m} \sum_{i=1}^{m} x_i = \bar{x}
\]

Library Statistical

Examples

- Mean(Fuel_price) → 1.19
- Mean(Skfuel_price) → 1.33

Sdeviation(x)

Returns an estimate of the standard deviation of x from its sample if x is probabilistic. If x is non-probabilistic, returns 0.

\[
\text{Sdeviation}(x) = \sqrt{\frac{1}{m-1} \sum_{i=1}^{m} (x_i - \bar{x})^2} = \sigma
\]

Library Statistical

Example

- Sdeviation(Fuel_price) → 0.10

Variance(x)

Returns an estimate of the variance of x if x is probabilistic. If x is non-probabilistic, returns 0.

\[
\text{Variance}(x) = \frac{1}{m} \sum_{i=1}^{m} x_i^2 - \bar{x}^2
\]
Skewness(x)

Returns an estimate of the skewness of \( x \). \( x \) must be probabilistic.

Skewness is a measure of the asymmetry of the distribution. A positively skewed distribution has a thicker upper tail than lower tail, while a negatively skewed distribution has a thicker lower tail than upper tail. A normal distribution has a skewness of zero.

**Skewness()** uses the formula:

\[
\frac{1}{m} \sum_{i=1}^{m} \left( \frac{x_i - \bar{x}}{\sigma} \right)^3
\]

Kurtosis(x)

Returns an estimate of the kurtosis of \( x \). \( x \) must be probabilistic.

Kurtosis is a measure of the peakedness of a distribution. A distribution with long thin tails has a positive kurtosis. A distribution with short tails and high shoulders, such as the uniform distribution, has a negative kurtosis. A normal distribution has zero kurtosis.

**Kurtosis(x)** uses the formula:

\[
\left( \frac{1}{m} \sum_{i=1}^{m} \left( \frac{x_i - \bar{x}}{\sigma} \right)^4 \right) - 3
\]
**Probability(b)**

Returns an estimate of the probability or array of probabilities that the Boolean value \( b \) is True.

- **Library**: Statistical
- **Example**: \( \text{Probability}(\text{Fuel\_price} < 1.19) \rightarrow 0.5 \)

**Getfract(x, p)**

Returns an estimate of the \( p \)th fractile (also known as quantile or percentile) of \( x \). This is the value of \( x \) such that \( x \) has a probability \( p \) of being less than that value. If \( x \) is non-probabilistic, all fractiles are equal to \( x \).

The value of \( p \) must be a number or array of numbers between 0 and 1, inclusive.

- **Library**: Statistical
- **Examples**
  - \( \text{Getfract}(x, 0.5) \) returns an estimate of the median of \( x \).
    - \( \text{Getfract}(\text{Fuel\_price}, 0.5) \rightarrow 1.19 \)
  - The following returns a table containing estimates of the 10\%ile and 90\%ile values, that is, an 80\% confidence interval.
    - \( \text{Index Fract} := [0.1, 0.9] \)
    - \( \text{Getfract}(\text{Fuel\_price}, \text{Fract}) \rightarrow \)
      - \( \text{Fract} \)

- **Library**: Statistical
- **Example**
  - \( \text{Kurtosis(Skfuel\_prices)} \rightarrow -0.48 \)

**Probbands(x)**

Returns an estimate of probability or "confidence" bands for \( x \) if \( x \) is probabilistic. Otherwise returns \( x \) for every band. The probabilities are specified in the Uncertainty Setup dialog box, Probability Bands option (see "Uncertainty Setup dialog box").

- **Library**: Statistical
- **Example**
  - \( \text{Probbands}(\text{Fuel\_price}) \rightarrow \)
    - \( \text{Probability} \)

<table>

<td>1.257</td>
<td>1.355</td>
</tr>
</tbody>
</table>

**Covariance(x, y)**

Returns an estimate of the covariance of uncertain variables \( x \) and \( y \). If \( x \) or \( y \) are non-probabilistic, it returns 0. The covariance is a measure of the degree to which \( x \) and \( y \) both tend to be in the upper (or lower) end of their ranges at the same time. Specifically, it is defined as:
Library Statistical

Suppose you have an array \( X \) of uncertain quantities indexed by \( I \),

\[
\text{Index } I := 1..5 \\
\text{Variable } X := \text{Array}(I, [...])
\]

you can compute the covariance matrix of each element of \( X \) against each other’s element (over \( I \)), thus:

\[
\text{INDEX } J := \text{CopyIndex}(I) \\
\text{Covariance}(X, X[I=J])
\]

We create index \( J \) as a copy of index \( I \) and then create a copy of \( X \) that replaces \( I \) by \( J \) so that the covariance is computed for each slice of \( X \) over \( I \) against each slice over \( J \). The result is the covariance matrix indexed by \( I \) and \( J \). Each diagonal element contains the variance of the variable, since \( \text{Variance}(X) = \text{Covariance}(X, X) \). You can use this same method to generate a correlation matrix using the \text{Correlation()} or \text{Rank_correl()} functions described below.

**Correlation(x, y)**

Returns an estimate of the correlation between the probabilistic expressions \( x \) and \( y \), where -1 means perfectly negatively correlated, 0 means no correlation, and 1 means perfectly positively correlated.

\[
\text{Correlation}(x, y)
\]

\( \), a measure of probabilistic dependency between uncertain variables, is sometimes known as the Pearson product moment coefficient of correlation, \( r \). It measures the strength of the linear relationship between \( x \) and \( y \), using the formula:

\[
\sum_{i} (x_i - \bar{x})(y_i - \bar{y}) \\
\sqrt{\sum_{i} (x_i - \bar{x})^2 \times \sum_{i} (y_i - \bar{y})^2}
\]

**Example**

With \text{sampleSize} set to 100 and number format set to two decimal digits:

\[
\text{Correlation}(\text{Alt_fuel_price} + \text{Fuel_price}, \text{Fuel_price}) \rightarrow 0.71
\]

Correlation of two independent, uncorrelated distributions approaches 0 as the sample size approaches infinity.

**Example**

With \text{sampleSize} = 20:

\[
\text{Correlation}(\text{Normal}(1.19,0.1), \text{Normal}(1.19,0.1)) \rightarrow -.28
\]

With \text{sampleSize} = 1000:
Chapter 16  Statistics, Sensitivity, and Uncertainty
Analysis

Statistical functions

Correlation(Normal(1.9, 0.1), Normal(1.9, 0.1)) → 0.03

**Rankcorrel(x, y)**

Returns an estimate of the rank-order correlation coefficient between the distributions \( x \) and \( y \). \( x \) and \( y \) must be probabilistic.

**Rankcorrel(x, y)**, a measure of the dependence between \( x \) and \( y \), is sometimes known as Spearman’s rank correlation coefficient, \( r_s \).

Rank-order correlation is measured by computing the ranks of the probability samples, and then computing their correlation. By using the rank order of the samples, the measure of correlation is not affected by skewed distributions or extreme values, and is, therefore, more robust than simple correlation. Rank-order correlation is used for importance analysis (see “Importance analysis”).

**Library**  Statistical

**Example**  With `sampleSize = 100`:

```
Rankcorrel(Fuel_price, Alt_fuel_price) → .02
```

**Frequency(x, i)**

If \( x \) is a discrete uncertain variable, returns an array indexed by \( i \), giving the frequency, or number of occurrences of discrete values \( i \). \( i \) must contain unique values; if numeric, the values must be increasing.

If \( x \) is a continuous uncertain variable and \( i \) is an index of numbers in increasing order, it returns an array indexed by \( i \), with the count of values in the sample \( x \) that are equal to or less than each value of \( i \) and greater than the previous value of \( i \).

If \( x \) is non-probabilistic, `Frequency()` returns `sampleSize` for each value of \( i \) equal to \( x \).

Since `Frequency()` is computed by counting occurrences in the probabilistic sample, it is a function of `sampleSize` (see “Uncertainty Setup dialog box”). If you want the relative frequency rather than the count of each value, divide the result by `sampleSize`.

**Library**  Statistical

**Example (continuous)**  

```
Index Index_a := [1.2, 1.25]
Frequency(Fuel_price, Index_a) →

Index_a
---
1.2 1.25
54 19
```

**Example (discrete)**  

Bern_out: [0, 1]

(Possible outcomes of the Bernoulli Distribution)

```
With SampleSize = 100:
Frequency(Bernoulli(0.3), Bern_out) →
Bern_out
---
0 1
70 30
```

```
With SampleSize = 25:

Mid(x)

Returns the mid value of x. Unlike other statistical functions, Mid() forces deterministic evaluation in contexts where x would otherwise be evaluated probabilistically.

The mid value is calculated by substituting the median for most full probability distributions in the definition of a variable or expression, and using the mid value of any inputs. The mid value of a variable or expression is not necessarily equal to its true median, but is usually close to it.

Library Statistical

Example Mid(Fuel_price) → 1.19

Sample(x)

Forces x to be evaluated probabilistically and returns a sample of values from the distribution of x in an array indexed by the system variable Run. If x is not probabilistic, it just returns its mid value. The system variable sampleSize specifies the size of this sample. You can set sampleSize in the Uncertainty Setup dialog box (see “Uncertainty Setup dialog box”).

Library Statistical

When to use Use when you want to force probabilistic evaluation.

Example Here are the first six values of a sample:

PDF(X) and CDF(X)

These functions generate histograms from a sample X. They are similar to the methods used to generate the probability density function (PDF) and cumulative probability distribution function (CDF) as uncertainty views in a result window as graph or table. But, as functions, they return the resulting histogram as an arrays available for further processing, display, or export. For example,

\[
\begin{align*}
\text{PDF}(X) \\
\text{CDF}(X)
\end{align*}
\]

evaluate \(x\) in prob mode, and returns an array of points on the density or cumulative distribution respectively.

You can also use PDF and CDF to generate a histograms (direct or cumulative) of data that is not uncertain, but indexed by something other than Run. For example, to generate a histogram of \(Y\) over index \(J\), specify the index explicitly:

\[
\text{PDF}(Y, J)
\]

If it decides that \(X\) is discrete rather than continuous, PDF generates a probability mass distribution and CDF generates a cumulative mass distribution, with a probability for each discrete value of \(X\). It uses the same method as the uncertainty views in results to decide if \(X\) is discrete — if it has text values, if it has many repeated numerical values, or if \(X\) has a Domain attribute that is discrete (see #xref Continuous or Discrete). Alternatively, you may control the result by setting the optional parameter discrete as true or false. For example:

\[
\begin{align*}
\text{Variable } X & := \text{Poisson}(20) \\
\text{PDF}(X, \text{Discrete: True})
\end{align*}
\]

generates a discrete histogram over \(x\). If \(x\) contains text values, i.e., categorical data, you may want to control the order of the categories, e.g., ["Low", "Medium", "High"]). You can do this by specifying the Domain attribute of \(x\) as a List of Labels with these values, or as an Index, referring to an Index using them. Alternatively, you can provide PDF or CDF with the optional Domain parameter provided as the list of labels. If \(x\) is an expression rather than a variable, this is your only choice.

PDF and CDF have one required parameter:

\[
X \quad \text{The sample data points, indexed by } i.
\]

and several optional parameters:

\[
\begin{align*}
i & \quad \text{The index over which they generate the histogram. By default this is Run (i.e., a Monte Carlo sample) but you can also specify another index to generate a histogram over another dimension.} \\
w & \quad \text{The sample weights. Can be used to weight each sample point differently. Defaults to system variable SampleWeights.} \\
\text{discrete} & \quad \text{Set true or false to force discrete or continuous treatment. By default, it guesses, usually correctly.} \\
\text{binMethod} & \quad \text{Selects the histogramming method used. Otherwise it uses the system default set in the Uncertainty Setup dialog from the Result menu. Options are:} \\
& \quad 0 \text{ "equal-X": Equal steps along the X axis (values of X).} \\
& \quad 1 \text{ "equal-sample-P": Equal numbers of sample values in each step.} \\
& \quad 2 \text{ "equal-weighted-P": Equal sum of weights of samples, weighted by } w.
\end{align*}
\]
Weighted statistics and w parameter

Normally, each statistical function gives an equal weight to each sample value in its parameters. You can use the optional parameter w for any statistical function to specify unequal weights for its samples. This lets you estimate conditional statistics. For example:

\[ \text{Mean}(X, \ w: X > 0) \]

computes the mean of x for those samples of x that are positive. In this case, the weight vector contains only zeros and ones. The expression \( x > 0 \) gives a weight of 1 (True) for each sample that satisfies the relationship and 0 (False) to those that do not.

By default, this method works over uncertain samples, indexed by \( \text{Run} \). You can also use it to compute weighted statistics over other indexes. For example, if \( Y \) is an array indexed by \( J \), you could compute:

\[ \text{Mean}(Y, I, W : Y > 0) \]

If you set the system variable \( \text{SampleWeighting} \) to something other than 1 (see “Importance weighting”, all statistical functions use \( \text{SampleWeighting} \) as the default weights, unless you specify parameter w with some other weighting array. So, when using importance weighting, all statistics (and uncertainty views) automatically use the correct weighting.

Importance analysis

In a model with uncertain variables, you may want to know how much each uncertain input contributes to the uncertainty in the output. Typically, a few uncertain inputs are responsible for the lion’s share of the uncertainty in the output, while the rest have little impact. You can then concentrate on getting better estimates or building a more detailed model for the one or two most important inputs without spending considerable time investigating issues that turn out not to matter very much.

The importance analysis features in Analytica can help you quickly learn which inputs contribute the most uncertainty to the output.

What is importance?

This analysis uses as a metric of the "importance" of each uncertain input to a selected output, the absolute rank-order correlation between each input sample and the output sample. It is a robust measure of the uncertain contribution because it is insensitive to extreme values and skewed distributions. Unlike commonly used deterministic measures of sensitivity, such as used in the Tornado analysis, it averages over the entire joint probability distribution. Therefore, it works well even for models where there are strong interactions, where the sensitivity to one input depends on the value of another.
Create an importance variable

1. Be sure you are in edit mode, viewing a Diagram window. Select an output variable, \( u \), that depends on two or more uncertain inputs — possibly, an objective.

2. Select Make Importance from the Object menu.

If the selected output is \( u \), it creates an index \( u_{Inputs} \), a list of the uncertain inputs, and a general variable, \( u_{Importance} \), containing the importance of those inputs to the output.

Example

Variable Miles\_per\_year := Triangular(1,12K,30K)
Variable Fuelcost\_per\_gallon := Lognormal(3)
Variable Miles\_per\_gallon := Normal(33,2)
Variable Fuel\_cost\_per\_year :=
\[
(\text{Fuel\_cost\_per\_gallon}\times\text{Miles\_per\_year})/\text{Miles\_per\_gallon}
\]

After you select Fuel\_cost\_per\_year and then Make Importance from the Object menu, the diagram contains two new variables.

Fuel\_cost\_per\_year\_inputs is a one-dimensional edit table of the chance variables. Its index contains the titles of the chance nodes, and its values are the identifiers of those nodes.

Fuel\_cost\_per\_year\_importance is defined as

\[
\text{Abs}(\text{Rankcorrel}(\text{Fuel\_cost\_per\_year\_inputs}, \text{Fuel\_cost\_per\_year}))
\]

The Rankcorrel() function computes the rank-order correlation of each input to the output, and then the Abs() function computes the absolute value, yielding a positive relative importance.
As expected, \textit{Fuelcost per gallon} contributes considerably more uncertainty to \textit{Fuel cost per year} than \textit{Miles per gallon}.

\textbf{Tip} \hspace{1cm} Importance, like every other statistical measure, is estimated from the random sample. The estimates may vary slightly from one computation to another due to random noise. For a sample size of 100, an importance of 0.1 may not be significantly different from zero. But an importance of 0.5 is significantly different from zero. The main goal is to identify two or three that are the primary contributors to the uncertainty in the output. For greater precision, use a larger sample size.

\textbf{Updating inputs to importance analysis} \hspace{1cm} If you create an importance analysis variable for \(U\), and later add or remove uncertain variables that affect \(U\), the uncertainty analysis is not automatically updated to reflect those changes. You may update the analysis either by:

- Select \(U\) and then select \textbf{Make Importance} from the \textit{Object} menu. It will automatically update the importance analysis to reflect any new or removed uncertain inputs.

- Draw an arrow from any new uncertain input into index \(U\) inputs. It will add the new variable as an uncertain input. Similarly, you can remove a variable from \(U\) inputs by redrawing an arrow from that variable into \(U\) inputs.

\section*{Sensitivity analysis functions}

Sensitivity analysis enables you to examine the effect of a change in the value of an input variable on the values of its output variables. They do not require their parameters to be uncertain.

\textbf{Examples} \hspace{1cm} The examples in this section refer to the following variables:

\begin{itemize}
  \item \textit{gasPrice} \hspace{1cm} \texttt{Normal(1.3, .3)} \hspace{1cm} Cost of gasoline per gallon within market fluctuations
  \item \textit{mpy} \hspace{1cm} \texttt{12K} \hspace{1cm} The average number of miles driven per year
\end{itemize}
Sensitivity analysis functions

Chapter 16  Statistics, Sensitivity, and Uncertainty Analysis

Dydx(y, x)

Returns the derivative of expression y with respect to variable x, evaluated at mid values. This function returns the ratio of the change in y to a small change in x that affects y. The "small change" is \( x / 10000 \), or 1.0E-6 if \( x = 0 \).

Library Special

Examples

Because fuelCost depends on mpg, a small change in mpg seems to have a modest negative effect on fuelCost:

\[
Dydx(fuelCost, mpg) \rightarrow -19.7
\]

The reverse is not true, because mpg is not dependent on fuelCost. That is, fuelCost does not cause any change in mpg:

\[
Dydx(Mpg, Fuelcost) \rightarrow 0
\]

In this model of fuelCost, a small change in gasPrice has by far the largest effect of all its inputs:

\[
Dydx(fuelCost, gasPrice) \rightarrow 428.6
\]

\[
Dydx(fuelCost, mpy) \rightarrow 0.04643
\]

Tip

When you evaluate DyDx() in mid mode, the mid value for x is varied and the mid value of y is evaluated. In prob mode, the sample of x is varied and the sample for y is computed in prob mode. Therefore, when y is a statistical function of x, care must be taken to ensure that the evaluation modes for x and y correspond. So, for example,

\[
Y := DyDx(Kurtosis( Normal(0, X ) ), X)
\]

Fuel consumption averaged over driving conditions

Annual cost of fuel

Probability density of fuelCost:

mpg: Normal(28, 5)
fuelCost: gasPrice * mpy / mpg
would not produce the expected result. In this case, when evaluating \( y \) in determ mode, Kurtosis evaluates its parameter, and thus \( x \), in prob mode, resulting in a mis-match in computation modes. To get the desired result, you should explicitly use the mid value of \( x \):

\[
Y := \text{DyDx(Kurtosis(Normal(0,Mid(X))), X)}
\]

**Elasticity\( (y, x) \)**

Returns the percent change in variable \( y \) caused by a 1 percent change in a dependent variable \( x \).

**Elasticity()** is related to \( Dydx() \) in the following manner:

\[
\text{Elasticity}(y,x) = \frac{\text{Dydx}(y,x)*(x/y)}
\]

**Library** Special

**Examples**

- **Elasticity(fuelCost, mpg) → -0.9901**
- **Elasticity(fuelCost, gasprice) → 1**

A 1% change in variables \textit{mpg} and \textit{gasPrice} cause about the same degree of change in \textit{fuelcost}, although in opposite directions.

\textit{mpg} is inversely proportional to the value of \textit{fuelCost}, while \textit{gasPrice} is proportional to it.

**Tip** When you evaluate **Elasticity()** in determ (mid) mode, the mid value for \( x \) is varied and the mid value of \( y \) is evaluated. In prob mode, the sample of \( x \) is varied and the sample for \( y \) is computed in prob mode. Therefore, when \( y \) is a statistical function of \( x \), care must be taken to ensure that the evaluation modes for \( x \) and \( y \) correspond.

**Whatif\( (e, v, vNew) \)**

Returns the value of expression \( e \) when variable \( v \) is set to the value of \textit{vNew}. \( v \) must be a variable. It lets you explore the effect of a change to a value without changing it permanently. It restores the original definition of \( v \) after evaluating \textit{Whatif()} expression, so that there is no permanent change (and so causes no side effects).

**Library** Special

**Example**

\[
\text{Fuelcost} \rightarrow 557.1
\]

\[
\text{Whatif(Fuelcost, Mpy, 14K)} \rightarrow 650
\]

**WhatIfAll\( (e, \text{vList}, \text{vNew}) \)**

Like **Whatif**, but it lets you examine a set of changes to a list of variables, \textit{vList}. It returns the mid value of \( e \) when each of variables in \textit{vList} is assigned the value in \( x \) one at a time, with the remaining variables remaining at their nominal values. The result is indexed by \textit{vList}. If \textit{vNew} is indexed by \textit{vList}, it assigns the corresponding value of \textit{vNew} to each variable, letting you assign a different value to each variable in \textit{vList}. **WhatIfAll()** is useful for performing \textit{ceteris paribus} style sensitivity analysis, which varies one variable at a time, leaving the others at their initial value, such as in Tornado charts (see next section for an example).
Suppose $Z$ is a function of $A$, $B$, and $C$, and we wish to examine the effect on $Z$ when each input is varied, one at a time, by 10% from its nominal value. Define:

- **Variable** $Z := 10*A + B^2 + 5*C$
- **Index** $L := [90\%,110\%]$
- **Variable** $V := [A, B, C]$
- **MyTornado** := WhatIfAll($Z, V, L*V$)

**Tornado charts**

A tornado diagram is a common tool used to depict the sensitivity of a result to changes in selected variables. It shows the effect on the output of varying each input variable at a time, keeping all the other input variables at their initial (nominal) values. Typically, you choose a "low" and a "high" value for each input. The result is then displayed as a special type of bar graph, with bars for each input variable displaying the variation from the nominal value. It is standard practice to plot the bars horizontally, sorted so that the widest bar is placed at the top. When drawn in this fashion, the diagram takes on the appearance of a tornado, hence its name. The figure below shows a typical tornado diagram.

**Create a tornado analysis** To perform a tornado analysis, you must:

1. Select the result or output variable to perform the analysis on.
2. Select the input variables which may affect the output.
3. Decide what the low and high values are to be for each input variable.

**Note**: The input variables do not need to be chance variables. In fact, tornado analysis is often applied to models with no chance variables.
Tornado charts

There are several options for selecting low and high values, including:

- Selecting the same absolute low and high levels for every input. This usually only makes sense if inputs are very homogeneous with identical nominal values.
- Selecting absolute low and high values separately for each input variable.
- Varying all inputs by the same relative amount, e.g., low=90% of nominal, high=110% of nominal.
- Varying all inputs between two given fractiles. This only makes sense if your inputs are uncertain variables. Example: Low=10% fractile, High=90% fractile, nominal=50% fractile.

Implementing a tornado analysis

For this example, assume we vary all inputs by the same amount.

1. Create an index variable containing a list of input variable identifiers. Suppose this is called Vars.
2. Create a variable, L, and define it as a self-indexed table. (To do this, select Table from the Expression pulldown, and select self as an index.) From the edit table, set the self-index labels to read low and high. Set the value corresponding to low to 90%, and set the value corresponding to high to 110%.
3. Create a node, Tornado_Analysis. Assume that the output variable is X. Define Tornado_Analysis as:
   \[
   \text{WhatIfAll}( \ X, \ Vars, \ L \times Vars )
   \]
4. Create a node, Sorted_Tornado_Inputs, defined as:
   \[
   \text{sortIndex}( \ abs(\text{Tornado_Analysis}[L='high'] - \text{Tornado_Analysis}[L='low']) )
   \]
5. Create a node, Sorted_Tornado, defined as:
   \[
   \text{Tornado_Analysis}[Vars=\text{Sorted_Tornado_Inputs}]
   \]

Steps 4 & 5 are not necessary if you do not require your bars to be displayed from largest to smallest. If you do include steps 4 & 5, Sorted_Tornado will contain the results of the tornado analysis, otherwise the result is Tornado_Analysis.

It is possible in Analytica to use array abstraction to produce a set of tornado diagrams, with each tornado itself indexed by an additional dimension. Additional dimensions are already included if your output variable is itself an array result, in which case you will have a tornado diagram for each element in the output value's array value. This flexibility is unique to Analytica; however, you should note that having multiple tornados in a single result complicates the problem of sorting the bars, since the sort order will, in general, be different for the different bars. If you have extra indexes in your tornado
Chapter 16  
Statistics, Sensitivity, and Uncertainty Analysis

analysis, you will need to either skip steps 4 & 5 above, and display non-sorted Tornadoes, or select a single sort order based on whatever criteria fits your needs, realizing that not all tornados will display in sorted order. To display a tornado using Excel graph, your output variable must be a scalar.

The WhatIfAll() function typically provides the easiest method for implementing a tornado analysis in Analytica. Note that the third parameter to WhatIfAll() controls the method by which inputs are varied for the analysis. For example:

- For the case where you select the same absolute low and high levels for every input, L would be set to the absolute low and high values, and the third parameter to WhatIfAll() would be simply L.
- For the case where you select absolute low and high values separately for each input variable, you would index L by Vars, fill in L’s table appropriately, then set the third parameter to be just L.
- And for the case where you vary all inputs between two given fractiles, you would set L to the desired fractiles, and use as the third parameter the expression: getFract(X,L).

Graphing a tornado  
It’s usually best to graph a tornado switching X and Y axis, so that the names of the input variables are listed down the vertical axis, and the effect on the output along the horizontal axis:

1. Select Show Result for the Tornado_Analysis or Sorted_Tornado variable. Press the Graph button if necessary.
2. Pivot the index order (if necessary) so that Vars is on the X-axis and L is the Key.
3. Select Graph Setup and then Graph Style.
4. Set the Line Style to the filled bar setting. Set Overlap=100%, origin=X. (Where X is your output variable of interest). Press Apply.

X-Y plots  
When evaluating a variable, you can specify another variable to view it against, for Mid, Mean, Statistics, Probability Bands, and Sample.

To graph one variable against another:

1. Open a Result window for the y- (vertical axis) variable.
2. Click the XY button [XY] located in the top right corner of the window to open the Object Finder dialog box.
3. In the Object Finder, select the x- (horizontal axis) variable.

The two variables in an XY window must share at least one index, and all indexes of x must also be indexes of y. The popup menu in the index selection area becomes Common Index — only indexes of both x and y may be selected.

Variable Degrees := Sequence(0,360,10)
Variable SinX := Sin(Degrees)
Cosine: Cos(Degrees) →
Click the XY button. In the Object Finder dialog under Current Module select the variable sine to display:
Chapter 16  Statistics, Sensitivity, and Uncertainty Analysis

Scatter plots

Click the Table View button to display:

To return to the graph or table of Cosine vs. Degrees, click in the XY check box.

A scatter plot graphs the samples of two probabilistic variables against each other, and provides insight into their probabilistic relationship.

To generate a scatter plot for two variables, X and Y:

1. Open a Result window for Y.
2. Click the XY button located in the top right corner of the window to open the Object Finder dialog box.
3. In the Object Finder, select the X variable.
4. In the Uncertainty View popup menu (at the top left of the Result window), select the Sample view.

If the variables are independent, the scatter plot points will fall randomly on the graph. If the variables are totally dependent, the scatter plot points will fall along a single line. The strength of the relationship is indicated by the degree to which the points are close to a line. If the line is straight, the relationship is linear; if the line is curved, the relationship is nonlinear.
Regression analysis

Regression is a widely used statistical method to estimate the effects of a set of inputs (independent variables) on an output (the dependent variable). It is a powerful method to estimate the sensitivity of the output to a set of uncertain inputs. Like the rank-correlation used in importance analysis (see “Importance analysis”), it is a global measure of sensitivity in that it averages the sensitivity over the joint distribution of the inputs, unlike Tornado analysis that is local, meaning it varies each variable one at a time, leaving all others fixed at a nominal value.

Regression() is in the built-in Statistics library, and works with all editions of Analytica. The logit and probit regression functions are in an add-in library, Generalized Regression.ana, and require Analytica Optimizer.

Regression(y, b, i, k)

Generalized linear regression. Finds the best-fit (least squared error) curve to a set of data points. Regression() finds the parameters $a_k$ in an equation of the form:

$$y = \sum_{k} a_k b_k(x)$$

Example

You can superimpose several scatter plots of $y$ in an array of uncertain quantities depending on $x$. The different quantities will be represented by differently colored dots or symbols.

**Example**

$X: \text{Uniform}(1,2)$

$Y: \text{Normal}(10,3)$

The resulting scatter plot, of two independent variables, is:
Chapter 16  Statistics, Sensitivity, and Uncertainty

Regression analysis

The data points are contained in $y$ (the dependent variable) and $b$ (the independent variables), both of which must be indexed by $i$. $b$ is the basis set and is indexed by $l$ and $k$. The function returns the set of parameters $a_k$ indexed by $k$.

With the generalized form of linear regression, it is possible to have several independent variables, and your basis set may even contain non-linear transformations of your independent variables. `Regression()` can be used to find the best-fit planes or hyperplanes, best-fit polynomials, and more complicated functions.

`Regression()` uses a state-of-the-art algorithm based on singular-value decomposition that is numerically stable, even if the basis set contains redundant terms.

**Example 1**

Suppose a set of $(x,y)$ points are contained in $x$ and $y$, both indexed by $i$, and we wish to find the parameters $m$ and $b$ of the best-fit line $y = mx + b$. We first define an index $k$ as a list of labels:

```plaintext
Index K := ['m','b']
```

Next, define $B$ as a table indexed by $K$:

```plaintext
Variable B := K |
<table>
<thead>
<tr>
<th>m</th>
<th>b</th>
</tr>
</thead>
<tbody>
<tr>
<td>X</td>
<td>1</td>
</tr>
</tbody>
</table>
```

`Regression(Y, B, I, K)` returns the coefficients $m$ and $b$ as an array indexed by $k$.

**Example 2**

We wish to fit the following polynomial to $(x, y)$ data:

$$y = a_5x^5 + a_4x^4 + a_3x^3 + a_2x^2 + a_1x + a_0$$

Define $k$ to be the list:

```plaintext
Variable B := [X^5,X^4,X^3,X^2,X,1]
```

`Regression(Y, B, I, B)` returns the best-fit coefficients of the polynomial indexed by $B$.

**Logistic_Regression(Y, B, I, K)**

Logistic regression is a technique for predicting a Bernoulli (i.e., 0,1-valued) random variable from a set of continuous dependent variables. See the Wikipedia article on Logistic regression for a simple description. Another generalized logistic model that can be used for this purpose is the `Probit_Regression` model. These differ in functional form, with the logistic regression using a logit function to link the linear predictor to the predicted probability, while the probit model uses a cumulative normal for the same.

This function requires Analytica Optimizer.

The `Logistic_regression` function returns the best-fit coefficients, $c$, for a model of the form:

$$\ln\left(\frac{p_i}{1-p_i}\right) = \sum_k c_kb_{i,k}$$
given a data set basis \( B \), with each sample classified as \( y_i \), having a classification of 0 or 1.

The syntax is the same as for the `Regression` function. The basis may be of a generalized linear form, that is, each term in the basis may be an arbitrary non-linear function of your data; however, the `logit` of the prediction is a linear combination of these.

When you have used the `Logistic_Regression` function to compute the coefficients for your model, the predictive model that results returns the probability that a given data point is classified as 1.

**Probit_regression(Y, B, I, K)**

A probit model relates a continuous vector of dependent measurements to the probability of a binomial (i.e., 0,1-valued) outcome. In econometrics, this model is sometimes called the Harvard model. The `Probit_regression` function infers the coefficients of the model from a data set, where each point in the training set is classified as 0 or 1.

Probit regression is very similar to `Logistic_regression`. Both are used to fit a binomial outcome based on a vector of continuous dependent quantities. They differ in their use of the `link` function.

Given a set of data points, indexed by \( I \), with each point classified as 0,1 in the \( Y \) parameter, and a set of basis terms, \( B \), containing the dependent variables (where the vector of dependent variables is indexed by \( K \)), the `Probit_regression` function finds and returns the set of coefficients for the probit model:

\[
\pi_i = \Phi \left( \sum_k c_k b_k \right)
\]

where \( \Phi \) is the inverse cumulative normal distribution function.

The basis, \( B \), is a function of the dependent variables in your data. Each element along \( K \) of the basis vector may be an arbitrary, even non-linear, combination of the data in your data set. However, the number of terms in the basis should be kept small relative to the number of data point in your data set.

**Library** Generalized Regression.ana

---

This function requires Analytica Optimizer.

---

**Uncertainty in regression results**

These functions help estimate the uncertainty in the results from a regression analysis, including uncertainty in the regression coefficients and the noise. Together they are useful for generating a probability distribution that represents the uncertainty in the predictions from a regression model. When applying regression to make projections into the future based on historical data, there may be additional sources of uncertainty because the future may be different from the past. These functions estimate uncertainty due to noise and imperfect fit to the historical data. You may wish to add further uncertainty for projections into the future to reflect these additional differences.
Chapter 16  Statistics, Sensitivity, and Uncertainty  Analysis

Uncertainty in regression results

RegressionDist(y, b, i, k)

RegressionDist estimates the uncertainty in linear regression coefficients, returning probability distributions on them. Suppose you have data where Y was produced as:

\[ Y = \text{Sum}(C\cdot B, K) + \text{Normal}(0, S) \]

S is the measurement noise. You have the data B[i,K] and Y[i]. You might or might not know the measurement noise S. So you perform a linear regression to obtain an estimate of C. Because your estimate is obtained from a finite amount of data, your estimate of C is itself uncertain. This function returns the coefficients C as a distribution (i.e., in sample mode, it returns a sampling of coefficients indexed by Run and K), reflecting the uncertainty in the estimation of these parameters.

Library  Multivariate Distributions.ana

Examples

If you know the noise level S in advance, then you can use historical data as a starting point for building a predictive model of Y, as follows:

{ Your model of the dependent variables: }
Variable Y := your historical dependent data, indexed by I
Variable B := your historical independent data, indexed by I,K
Variable X := { indexed by K. Maybe others. Possibly uncertain }
Variable S := { the known noise level }
Chance C := RegressionDist(Y,B,I,K)
Variable Predicted_Y := Sum(C\cdot X, K) + \text{Normal}(0,S)

If you don’t know the noise level, then you need to estimate it. You’ll need it for the normal term of Predicted_Y anyway, and you’ll need to do a regression to find it. So you can pass these optional parameters into RegressionDist. The last three lines above become:

Variable E_C := Regression(Y,B,I,K)
Variable S := RegressionNoise( Y,B,I,K,E_C )
Chance C := RegressionDist(Y,B,I,K,E_C)
Variable Predicted_Y := Sum(C\cdot X, K) + \text{Normal}(0,S)

If you use RegressionNoise to compute S, you should use Mid(RegressionNoise(...)) for the S parameter. However, when computing S for your prediction, don’t use RegressionNoise in context. Better is if you don't know the measurement noise in advance, don’t supply it as a parameter.

RegressionFitProb(y, b, i, k, c)

When you’ve obtained regression coefficients C (indexed by K) by calling the Regression function, this function returns the probability that a fit this poor would occur by chance, given the assumption that the data was generated by a process of the form:

\[ Y = \text{Sum}(C* B, K) + \text{Normal}(0, S) \]

If this result is very close to zero, it probably indicates that the assumption of linearity is bad. If it is very close to one, then it validates the assumption of linearity.

Library  Multivariate Distributions.ana

This is not a distribution function — it does not return a sample when evaluated in sample mode. However, it does complement the multivariate RegressionDist function also included in this library.
Example To use, first call the Regression function, then you must either know the measurement knows a priori, or obtain it using the RegressionNoise function.

\[
\text{Var } E_C := \text{Regression}(Y, B, I, K);
\]

\[
\text{Var } S := \text{RegressionNoise}(Y, B, I, K, C);
\]

\[
\text{Var PrThisPoor := RegressionFitProb}(Y, B, I, K, E_C, S)
\]

RegressionNoise(y, b, i, k, c)

When you have data, \(Y[I]\) and \(B[I, K]\), generated from an underlying model with unknown coefficients \(C[k]\) and \(S\) of the form:

\[
Y = \text{Sum}( C*B, I) + \text{Normal}(0, S)
\]

This function computes an estimate for \(S\) by assuming that the sample noise is the same for each point in the data set.

When using in conjunction with RegressionDist, it is most efficient to provide the optional parameter \(C\) to both routines, where \(C\) is the expected value of the regression coefficients, obtained from calling Regression(Y,B,I,K). Doing so avoids an unnecessary call to the built-in Regression function.

Library Multivariate Distributions.ana

These functions express uncertainty in the coefficients of a linear regression. If you are using results form a linear regression, you can use these functions to estimate uncertainty in predictive distributions.

These uncertainties reflect only the degree to which the regression model fits the observations to which it was fit. They do not reflect any possible systematic differences between the past process that generated those observations and the process generating the results being predicted, usually in the future. In this way, they are lower bounds on the true uncertainty.
Chapter 17

Dynamic Simulation

This chapter shows you how to use the system function `Dynamic()` and the system variable `Time`. 
A dynamic variable is a quantity that changes over time — for example, the effect of inflation on car prices over a ten-year period. The system function Dynamic() and system variable Time enable you to model changes over time.

**Tip**
Read Chapter 11, “Arrays and Indexes,” before using these features.

The term dynamic is used in this chapter to refer to the Dynamic() function.

### The Time index

Dynamic simulation time periods are specified in the system variable Time. To perform dynamic simulation, you must provide a definition for Time.

To edit the definition of Time, select Edit Time from the Definition menu to open the Object window for Time.

Time is defined by default as a list of three numbers 0, 1, and 2. You may want to define Time as a list of years, as in the following example:

![Object window for Time](image)

Time becomes the index for the array that results from the Dynamic() function.

**Tip**
A model can have only one definition Time — that is, one set of time periods for Dynamic() functions. Any number of variables in the model can be defined using Dynamic().

### Using the Dynamic() function

Dynamic(initial1, initial2..., initialn, expr)

Performs dynamic simulation, calculating the value of its defined variable at each element of Time. The result of Dynamic() is an array, indexed by Time.
Using the Dynamic() function

**Initial**, ...**initial** are the values of the variable for the first \( n \) time periods. **expr** is an expression giving the value of the variable for each subsequent time period. **expr** can refer to the variable in earlier time periods, that is, contain its own identifier in its definition. If variable **Var** is defined using **Dynamic()**, **expr** can be a function of **Var[Time-k]** or **Self[Time-k]**, where \( k \) is an expression that evaluates to an integer between 1 and \( t \), and \( t \) is the time step at which **expr** is being evaluated.

**Tip**

Square brackets ([ ]) are necessary around **Time-t**.

The **Dynamic()** function must appear at the topmost level of a definition. It cannot be used inside another expression.

When a dynamic variable refers to itself, it appears in its own list of inputs and outputs, with a symbol for cyclic dependency: ⚫️.

**Library**

Special

**When to use**

Use **Dynamic()** for defining variables that are cyclically dependent. This is the only function in Analytica that permits reference to the same variable, or other dynamic variables, at earlier time periods.

**Example**

**Dynamic()** can be used to calculate the effect of inflation on the price of gasoline in the years 1990 to 1994.

If the initial value is $1.20 per gallon and the rate of inflation is 5% per year, then **Gasprice** can be defined as:

\[
\text{Dynamic}(1.2, \text{Gasprice}[\text{Time-1}] \times 1.05)
\]

or

\[
\text{Dynamic}(1.2, \text{Self}[\text{Time-1}] \times 1.05)
\].

Clicking the **Result** button and viewing the mid value as a table displays the following results:
For 1990, Analytica uses the initial value of `Gasprice (1.2)`. For each subsequent year, Analytica multiplies the value of `Gasprice` at `[Time-1]` by 1.05 (the 5 percent inflation rate).

\[x [ \text{Time-k} ]\]

Given a variable \(x\) and brackets enclosing \(\text{Time}\) minus an integer \(k\), returns the value for \(x\), \(k\) time periods back from the current time period. This function is only valid for variables defined using the `Dynamic()` function.

**Library**  Special

## More about the Time index

### Reference to earlier time

`Time-k` in the expression `var[Time-k]` refers to the position of the elements in the `Time` index, not values of `Time`.

For example, if `Time` equals \([1990, 1994, 1998, 2002, 2006]\), then the value of `Gasprice[Time-3]` in year 2006 would refer to the price of gasoline in 1994, not 2003. When you refer to the `Time` variable directly, not as an index, the expression refers to the values of `Time`. For example, the expression `(Time-3)` in 2006 is 2003.

The offset, \(k\), may be an expression, and may even be indexed by `Time`. When \(k\) is indexed by `Time`, then the offset varies at different points in `Time`. However, `Slice(k, Time, t)` must be between 1 and \(t-1\). It must be positive since the expression is not allowed to depend on values in the future (that have not yet been computed). It must be less than \(t-1\) since the expression cannot depend on values "before the beginning of time."

### Defining time

There are three ways to define the `Time` index, each of which has different advantages:
• Sequence (the preferred method)
• List (numeric)
• List of labels (text)

**Time as a sequence**

Using the `Sequence()` function is the easiest way to define time with equal intervals (see “List vs. list of labels” and “Creating an array with an edit table”). The numeric values for time can be used in other expressions.

**Example**

![Sequence example](image)

**Time as a list (numeric)**

When time is defined as a numeric list, it will usually consist of increasing numbers. The intervals between entries can be unequal, and the values for time can be used in other expressions.

**Example**

![List example](image)

When you use time periods that differ by a value other than 1, typing `(time-1)` won’t provide the value of the previous time period. You can use the syntax `x[time-1]` if you want to utilize a variable indexed by `time`, but if you want to perform an operation that depends on the difference in time between the current time period and the last one, you must first create a node that uncumulates the time index:

**YearsPassed: Uncumulate(time)**

![Uncumulate example](image)

Now you can include this node in a dynamic expression that depends on the time between time periods. The following definition is equivalent to the `Dynamic()` definition but allows for changes in time period increments:
Gasprice: Dynamic(1.2, Gasprice[Time - 1] * 1.05 ^ YearsPassed) → 

**Time as a list of labels (text)**

When `Time` is defined as a list of labels, `Time` values cannot be used in other expressions as numbers.

The resulting graph of any `Dynamic()` function, with the x-axis set to `Time`, will show the labels at equal x-axis intervals.

**Example**  

```
Time:  
| Jan | Feb | Mar | Apr |
```

Gasprice: Dynamic(1.2, Gasprice[Time-1] * 1.05) →
Using Time in a model

You can use Time like any index variable; you can change only its title and definition. To include the Time node on a diagram:

1. Open the Object window for Time by selecting Edit Time from the Definition menu.
2. Select Make Alias from the Object menu (see “An alias is like its original”).

When the time node displays on a diagram, arrows from Time to all dynamic variables display by default.

Initial values for Dynamic

A dynamic definition of var usually includes the expression Self[Time-k] or var[Time-k], where k is the number of time periods to subtract from the current Time value. You must supply at least 1 initial value.

As an example, when k in [Time-k] is greater than 1, suppose your car insurance policy depends on the premium you paid two years ago. To calculate your payments in 1992, you must refer to the amount paid in 1990. A dynamic variable representing such a rate for insurance needs two initial values for Time, such as:

Insurance:
Dynamic(600, 700, Insurance[Time - 2] * 1.05) →
Using arrays in Dynamic()

The initial value of a dynamic variable — that is, the first parameter to the Dynamic() function — can be a number, variable identifier, or other expression that evaluates to a single number, list, or array. Analytica evaluates a dynamic variable starting from each initial value, in each time period, so the result is a correctly dimensioned array.

Example

Expanding the example (see "Using the Dynamic() function"), suppose the inflation rate of gasoline is uncertain. Instead of providing a single numerical value, you could define the inflation rate as a list:

Using the new Inflation variable in the definition for Gasprice, the results show three different rates of increases in gasoline prices from 1990 to 1994:

Gasprice:
Dynamic(1.2, Gasprice[Time - 1] * (1 + Inflation)) →
Dependencies with Dynamic

All variables with dynamic inputs are evaluated dynamically — that is, their results are arrays indexed by Time.

Example A series of dynamic definitions produce equations for distance, velocity, and acceleration:

- Acceleration: -9.8
- Dt: 0.5
- Time: Sequence(0, 6, Dt)
- Velocity: Dynamic(0, Self[Time-1] + Acceleration * Dt)
- Distance: Dynamic(100, Self[Time-1] + Velocity * Dt)
Dynamic dependency arrows

If a variable is dynamically dependent on another variable, a gray arrow is drawn between the variables.

To show or hide dynamic dependency arrows:

1. Select Set Diagram Style from the Diagram menu to open the Diagram Style dialog box (see “Diagram Style dialog”).
2. Click in the Dynamic checkbox to show dynamic arrows (or uncheck it to hide the arrows).
3. Click OK to accept the change.

Expressions inside dynamic loops

A dynamic loop is a sequence of variables beginning and ending at the same variable, with each consecutive variable dependent on the previous one. At least one variable in a dynamic loop is defined using the dynamic function.

When the definition of a variable in a dynamic loop is evaluated, the definition is repeatedly evaluated in the context of Time=t (as t increments through the values of Time). The value for any identifier that appears in an expression is implicitly sliced at Time=t (unless it is explicitly offset in Time). As an example, suppose A is indexed by Time, and X is defined as:

\[
\text{Dynamic}(0, \text{self}[\text{Time}-1] + \text{Max}(A, \text{Time}))
\]

During evaluation, A would be an atom at any given time point since it is implicitly sliced across Time. When A is not indexed by Time, Max(A, Time) simply returns A, so that the above expression is equivalent to

\[
\text{Dynamic}(0, \text{self}[\text{Time}-1] + A)
\]

To add the greatest value of A along Time in this expression, you must introduce an extra variable to hold the maximum value, defined simply as Max(A, Time), and ensure that the two variables do not occur in the same dynamic loop.

If you attempt to operate over the Time dimension from within a dynamic loop, Analytica issues the warning: "Encountered application of an array function over the Time index from within a dynamic loop. The semantics of this operation may be different than you expect."

Uncertainty and Dynamic

Uncertain variables propagate uncertainty samples during dynamic simulation. If an uncertain variable is used in a dynamic simulation, its uncertainty sample is calculated only once, in the initial time period.

Example

The following definitions model population changes over time:

\[
\text{Variable Population} := \text{Normal}(30, 2) \\
\text{Variable Birthrate} := \text{Normal}(1.2, .3) \\
\text{Time} := 1 .. 10 \\
\text{Variable Pop_by_year} := \text{Dynamic}(\text{Population}, \text{Self}[\text{Time}-1] + \text{Birthrate})
\]
The uncertainty samples for Population and Birthrate are each calculated once, at the initial time period. The same samples are then used for each subsequent time period.

**Resampling**

If you want to create a new uncertainty sample for each time period (that is, resample for each time period), place the distribution in the last parameter of the Dynamic() function. For example, replace Birthrate with its definition in Pop_by_year:

```
Pop_by_year: Dynamic(Population, Self[Time - 1] + Normal(1.2, .3))
```

An alternative way to create a new uncertainty sample for each time period is to make Birthrate a dynamic variable.

```
Birthrate: Dynamic(Normal(1.2, .3), Normal(1.2, .3))
```

```
Pop_by_year: Dynamic(Population, Self[Time-1] + Birthrate)
```
OLE linking makes it possible to link data to and from external applications. With OLE linking, changes to inputs or results are automatically and instantaneously propagated between applications.

This chapter describes how to exchange data between Analytica and other applications. The primary methods are:

- Using the standard **Copy** and **Paste** commands
- Using OLE linking
- Using the **Import** and **Export** commands
Copying and pasting

You can use the standard **Copy** and **Paste** commands with any modifiable attribute of a variable, module, or function.

**Pasting data from a spreadsheet**

To paste tabular data from a spreadsheet into an Analytica table:

1. Select a group of cells in a spreadsheet.
2. Select **Copy** from that program’s **Edit** menu, to copy the data to the clipboard.
3. Bring the Analytica model to the front and open the **Edit Table** window you want to paste the data into.
4. Select a top-left cell or the same number of cells that you originally copied.
5. Select **Paste** from the **Edit** menu (**Control+v**).

**Tip**  
When copying a row of data from a spreadsheet into a one-dimensional table, transpose the data first so that you are copying it as a column of cells, not a row of cells.

**Pasting data from another program**

To paste data from a program other than a spreadsheet:

- Use tab characters to separate items, and return characters to separate lines.
- Use numbers in floating point or exponential format. You can use the suffixes that Analytica recognizes (including K, M, and m; see Character Suffixes for a comprehensive list). Dollar signs ($) and commas (thousands separators) are not permitted.

**Copying a diagram**

To copy an influence diagram, including the objects represented by the nodes:

1. Select the group of nodes you wish to copy.
2. Select **Copy** from the **Edit** menu (**Control+c**). The objects that the nodes represent, as well as a picture of the selected nodes with all of the relevant arrows between the selected nodes, are copied to the clipboard.

To copy an entire Influence Diagram window, select **Copy Diagram** from the **Edit** menu. The *entire* influence diagram is copied as a picture representation without copying the objects that the nodes represent.

**Copying an edit table or result table**

To copy data from an edit table or result table:

1. Open the window containing the table.
2. Select cells and choose **Copy** from the **Edit** menu (**Control+c**).

To copy all the elements of a table in addition to the index elements, select **Copy Table** from the **Edit** menu. The entire multidimensional array is copied as a graphic and as a list of two-dimensional tables in a special text format (see “Edit table data import/export format”).

**Copying a result graph**

To copy or export a result graph:

1. Open the **Result** window containing the graph.
2. Select **Copy** from the **Edit** (**Control+c**) menu to copy a PICT representation of the graph.
Using OLE to link results to other applications

Object Linking and Embedding (OLE) is a widely used Microsoft technology that enables objects in two applications to be hotlinked, so that changes to the object in one application cause the same changes in the other application. For example, by linking an array in Analytica to a table in a Microsoft Excel spreadsheet, any change to the array in the Analytica model is automatically reflected in the spreadsheet.

By using OLE linking, results from Analytica models can be linked into OLE compliant applications like Word and Excel. Linking data can save a great deal of work because it saves you from performing repeated copy and paste operations between Analytica and other applications whenever your model results change. Without OLE, if you copied result tables from Analytica, pasted them into a Word document, and later you tweak your model results, you would need to re-copy and re-paste all those result tables. However, if you link those tables using OLE, all the data in the Word document will update either automatically, or if you prefer, when you explicitly decide to update the data.

You may link any of the result table views (i.e., Mid, Mean, Statistics, Probability Density, Cumulative Probability, and Sample table views). You may link any two-dimensional slice of a multi-dimensional table with the regular Copy command. For result tables with more than two dimensions, you may decide to link the entire table as a series of two-dimensional tables using the Copy table option from the Edit menu. You may also link a rectangular region of cells that are a subset of a a two-dimensional table. However, you cannot link non-table data such as the information that is contained in the Object window or Attribute panel.

Linking procedure

Steps for linking result data from your Analytica model to an external OLE-compliant application are as follows. For concreteness, we’ll assume here that the other application is Microsoft Excel.

1. In the Analytica Result window, select the cells you want to link and choose Copy from the Edit menu.
2. From Excel, select the cells where you would like the Analytica data linked.
3. From Excel, choose Paste Special from the Edit menu.
4. The Paste Special dialog box will appear.
5. In this box, choose the option Paste Link, select Text from the As list, and click the OK button.

You’re done. Any changes to the source result table will be propagated to the linked data in Excel. The procedure for linking Analytica model results to other OLE-compliant applications will be similar to the above steps.

Tip

The external application must support OLE-linking of tab-delimited text data. Applications that do not support this format will not display "Text" as an option in Step 5 above, or will disable the Paste Special menu item in Step 3.
Detailed example of linking Analytica results

This example itemizes detailed steps for linking an Analytica result table into an Excel spreadsheet. Suppose you would like to link the model results displayed above into an Excel spreadsheet. You can start by linking the column and row headers. Go to the node titled Cashflow Category and evaluate its result. Notice the result of node Cashflow Category is displayed as a column of cells, but you would like to have them linked into Excel as a row. Unfortunately you may not link this data as a row with a single Copy/Paste Special operation since Excel will not let you transpose the linked data from a column to a row. However, you can easily work around this limitation. Link the values into an unused portion of your spreadsheet or to a blank sheet using the linking procedure described in the previous section. In the cells where you actually would like the labels to appear as a row, simply reference the linked cells. In other words, define the cells that will comprise the column headers for the linked table you are creating using the names of the corresponding linked cells.

Now it’s time to link the values of Time as the row headers in your linked table. Time is an Analytica system variable and one of the elementary ways to copy its values for linking is to create a node called Time and give it the definition time. Evaluate this node and then link the values displayed in the result table using the linking procedure described in the previous section.

Linking the body of the table is just a straightforward application of the linking procedure. The number format of the cells will be preserved in fixed point format, but you may want to use Excel formatting to get the dollar sign and thousand separator displayed. Excel may switch to the exponential number format or display ‘########’ if your columns are not wide enough.

The body of the table and its indexes (the row and column headers) are linked. For instance, if your Analytica model results change and you decide also to change the value of cost to expense, these changes will be reflected in your linked table in Excel (see the figure below).
Chapter 18 Importing, Exporting, and OLE Linking Data

Using OLE to link results to other applications

Important notes about linking to Analytica results

**Changing file locations**
When moving linked files from one drive partition to another on the same machine or between two different computers, keep the relative paths the same. The simplest way to do this is to keep the linked model files and the other application files to which they are linked in the same folder.

**Automatic vs. manual updating**
OLE links are set for *automatic* updating by default, but you may change this setting to *manual*. We recommend this if the data is linked from an Analytica model with a lengthy re-computation time or to an application with a lengthy re-computation time.

To change a link's setting to *manual* in Word:

1. On Word's *Edit* menu, select *Links*.
2. In the *Links* box that appears select the link(s) you're interested in adjusting.
3. Click the radio button labeled *manual* and click the *OK* button.

In other OLE-compliant applications the steps for switching from *automatic* to *manual* updating should be very similar to the ones listed above.

You may also decide to set all your OLE links to be updated manually using a preference setting in Analytica. From the *Edit* menu, select *Preferences*, then in the *Preferences* dialog box, uncheck the check box located on the bottom right labeled *Auto recompute outgoing OLE links*.

**Using Indexes**
Array-valued results that are to be linked should not have local indexes (created using the *Index..Do* construct). All indexes should correspond to index nodes in your diagram.

**Number formatting**
When linking data into OLE compliant applications, the number format will be the same as Analytica's format at the time of link creation. However, if the linked Analytica data uses the default Suffix number format, the linking will convert the format to *Exponential*, which is more universally recognizable in other applications. In programs that have their own number formatting settings such as Excel, the number format will likely be adjusted according to the settings for the cells you are pasting into. However you must still be careful about losing significant digits (see next paragraph).

Precision is another important issue in number formatting. Before linking from Analytica, you should first adjust the number format so that it displays all the significant digits you would like to have in the other OLE-savvy application to which you are linking.
Refreshing links when Analytica model is not running

If you refresh the links between an Analytica model and another OLE-savvy application when the Analytica model is not running, the following events will occur:

1. A new instance of Analytica is launched
2. It automatically loads the Analytica model
3. It evaluates the variables upon which the links are dependent,
4. It reactivates the links, and
5. It updates the linked data.

There are two ways to refresh the links this way. The first case occurs when a file with links is opened while the model file to which it is linked is closed, and you answer 'Yes' to the dialog box prompting you to update the linked data. The other way is if you are working with a file containing links to a model that is not running and you explicitly update the links. To explicitly update the links in Excel, you would select Links from the Edit menu. Then in the Links dialog box, select the links you would like to refresh and click the Update button.

Linking data from other applications into Analytica

Using OLE linking, you may incorporate data originating in OLE-compliant applications as the input for nodes in your Analytica model. You accomplish this by linking the external data to edit tables in Analytica. Once again, this removes the need to perform numerous copy and paste operations each time the source data in the other application changes.

When linking data into Analytica, you may link data into any edit table with less than three dimensions. When linking data in edit tables you must link all the contents of the table; linking a subset of an edit table is not supported. You may not link data from other applications to anywhere else than an edit table in Analytica including the diagram windows, Object windows, and the Attribute panel.

Linking procedure

Steps for creating a linked edit table in Analytica with data from an Excel spreadsheet:

1. In Excel, select the cells you want to link to Analytica and choose Copy from the Edit menu.
2. In Analytica, make the edit table where you want the Excel data linked the front most window.
3. From the Edit menu or the right mouse button pop-up menu, choose Paste Special and the Paste Special dialog box will appear.
4. In this box, choose the option Paste Link, select Text from the As list, and click the OK button.

The process for linking data from Word or other OLE compliant applications will be analogous to the steps just outlined.

Example of linking a table into Analytica

This section itemizes detailed steps for linking a table from Excel into Analytica by creating a node with a "Linked Table" definition. Specifically, suppose you desire to link the Excel table displayed in the following figure into Analytica.
Start by creating two indexes in Analytica to store the row and column headers. Title the first index *Items* and the second *Status*. Select the node *Items* and then click the **Show definition** button on the toolbar (this is the button with the pencil icon) or right mouse menu. In the **Attribute** panel or **Object** window that appears, click the **expr** popup menu and choose **List of Labels**. Press the down arrow or **Return** key three times. This will give you three cells — *item 1*, *item 2* and *item 3*. In Excel, copy the three cells used as the row headers (i.e., *Red Widgets*, *Blue Widgets*, and *Green Widgets*); return to Analytica and do a regular paste into the three cells of the definition for the Index node *Items*.

Now you need to copy the values of the column headers (i.e., *In Stock* and *Ordered*) into the definition for the index node *Status*. Since Analytica enforces strict dimension checking (i.e., you cannot paste a 3 x 1 array of cells into a 1 x 3 array of cells), you are required to first convert the row into a column. You can accomplish this easily by copying the row, moving to an unused portion of the spreadsheet or onto a blank sheet, and choosing **Paste special** from Excel's **Edit** menu. The **Paste Special** dialog box will appear and you need only select the **Transpose** check box on the bottom right. Click the **OK** button and you have converted the column header cells from a row into a column. Now copy this column, go back to Analytica, select the *Status* node, and click the **Show definition** toolbar button. Select the first cell 'item 1' and choose **Paste** from the Analytica's **Edit** menu.

Since you've finished creating the indexes, you're ready to start on the node that will contain the linked table. Create a variable node in Analytica and title it *Inventory*. With this node selected, click the **Show definition** button on the toolbar. In the **Attribute** panel or **Object** window that appears, click the **expr** popup menu and choose **Table**. The **Indexes** dialog appears. In this dialog, select *Items* and click the **▼** button. This will move *Items* to the **Selected Indexes** section. You also want to select *Status* and then click the **▼** button to make it a selected index as well. Click the **OK** button and an edit table will appear as follows.
Go to Excel and select the numerical values displayed in the table and choose **Copy** from the **Edit** menu. Return to Analytica (while in edit mode) and click anywhere in the edit table grid. Choose **Paste Special** from the **Edit** menu and the **Paste Special** dialog box comes into view. You want the settings in the box to be **Paste Link** and **Text** which are the default settings (see below). Click **OK**.

The caption for the table changes from **Edit Table** to **Linked Table** and you're done. If you arrange the application windows so that you can see the source table in Excel and the linked table in Analytica, you can readily demonstrate that the link is activated. Change the value for **Green Widgets Ordered** from 2 to say 17. The corresponding value in Analytica's linked table will change accordingly.
Tip  The data within the table is linked and will be updated automatically when altered, but the row and column headers are not linked and any changes to their values will have to be propagated using the standard cut and paste operations. Perform this by copying to the indexes used by the table, not to the table itself.

Important notes about linking into Analytica edit tables

Changing file locations  When moving linked files on the same machine or between two different computers, keep the relative paths the same so that the files can locate each other. The simplest way to do this is to keep the linked model file(s) and the other application file(s) to which it is linked in the same folder.

Automatic vs. manual updating  OLE links are set for ‘automatic’ updating by default, but you may change this setting to ‘manual’. This may be desirable if the linked data is used in a model with a lengthy computation time. To change a link’s setting to ‘manual’ updating:

1. On Analytica’s Edit menu, select OLE Links.
2. In the Edit Analytica Links box that appears select the link(s).
3. Click the radio button labeled manual and click the OK button.

Terminating links  You may want to terminate a link to a source file for a number of reason including if you do not have the source file or if you would like to edit the values in a linked table. To break a link, bring up the Edit Analytica Links dialog, by choosing OLE Links from the Edit menu. Select the link you would like to terminate and click the Break Link button.

Activating the other application  If you have linked data from an external application into Analytica, after loading Analytica you can make the other application visible using the Open Source button on the OLE Links dialog, accessed through the Edit menu. If you implement a portion of your model in Analytica and a portion in an external application, with OLE links in both directions, you can make both applications simultaneously visible on the screen by loading the Analytica model first, then pressing the Open Source button to open the external application.
Importing and exporting

Importing a definition To import a definition from a text file into expression format:

1. Select the definition field of the variable in either the Object window or Attribute panel definition view.
   If the variable is defined as a List, List of Labels, or Edit Table, select the cell(s) in which to import.

2. Select Import from the File menu. A dialog box prompts you for the file name from which to import.

Importing into an edit table To import data from a tab-delimited text file into an edit table:

1. Open the window containing the table.

2. Select cells and choose Import from the File menu.
   A dialog box prompts you for the file name from which to import.

   To import all the elements of a multidimensional table including the index elements, a special text format is required (see “Edit table data import/export format” on page 319). This is also the format in which an edit table or result table is exported. The indexes of the table must have been previously created as nodes.

Exporting To export a variable’s definition or result table to a text file, first be certain that the text file is closed.

1. Select the variable to be exported from and open either the Object window, definition in the Attribute panel or Result window.

2. Select the definition field, list cell(s), or table cell(s) for exporting.

3. Select Export from the File menu. A dialog box prompts you for the file name to export to.
Printing to a file

Another way of exporting any Diagram window, Object window, or Result window to a file is to print to a file:

1. Select Print from the File menu.
2. Select Print to File and press Enter or click OK.

3. Enter the name of the file and the format for the file in the dialog box that appears.

Edit table data import/export format

Multidimensional data being imported or copied into an edit table must be in a text file with the special format described in this section. This is also the format in which an edit table or result table is exported.

- **TextTable** is a keyword.
- **Attribute** is the name of the attribute into which the data is to be pasted (usually definition).
- **Variable identifier** is the identifier of the variable node into which the data is to be pasted.
- **Index identifier** is the identifier of the index for this variable. This node must already exist in the model.
- Each index value and array value pair must be separated by tab characters.
One-dimensional array

The format for a one-dimensional array is:

```
TextTable <Attribute> <Variable identifier>
<Line break>
<tab><Index identifier><Line break>
[Index value><tab><Array value><Line break>
```

Example

```
Keyword  Attribute    Variable identifier
TextTable Definition House_cost_inputs
House_inputs

PropTax  3400
Tax rate  0.44
Maintenance  4000
Interest  0.105
Appreciation  0.08
```

Two-dimensional array

The format for a two-dimensional array is:

```
TextTable <Attribute> <Variable identifier>
<Line break>
<Index1 identifier><tab><Index1 values separated by tabs><Line break>
<Index2 identifier><Line break>
<Index2 value1><tab><Array values separated by tabs><Line break>
<Index2 value2><tab><Array values separated by tabs><Line break>
<Index2 valueN><tab><Array values separated by tabs><Line break>
```
Example

Three-dimensional array

The format for a three-dimensional array is:

```
TextTable <Attribute> <Variable identifier> <line break>
<Index1 identifier><tab><Index1 Value1><line break>
<Index2 identifier><tab><Index2 values separated by tabs><line break>
<Index3 identifier><line break>
<Index3 value1><tab><Array values separated by tabs><line break>
<Index3 value2><tab><Array values separated by tabs><line break>
<Index3 valueN><tab><Array values separated by tabs><line break>
<Index1 identifier><tab><Index1 Value2><line break>
<Index2 identifier><tab><Index2 values separated by tabs><line break>
<Index3 identifier><line break>
<Index3 value1><tab><Array values separated by tabs><line break>
<Index3 value2><tab><Array values separated by tabs><line break>
<Index3 valueN><tab><Array values separated by tabs><line break>
```

and so on for each value of \texttt{Index1}.

\begin{tabular}{|c|c|c|}
\hline
\textbf{TextTable Definition Mortgage} & \textbf{Down payment} & 20000 45000 60000 \\

</tr>
</tbody>
</table>
```

Number format

Numerical data can be imported in any format recognized by Analytica (see “Number formats”).

Numerical data will be exported in the format set for the table, with these exceptions:

- Suffix format numbers will be exported in scientific exponential format.
- Fixed decimal point numbers of more than 9 digits will be exported in scientific exponential format.
- If a date format begins with the day of the week, e.g., "Saturday, January 1, 2000", the weekday is suppressed: "January 1, 2000".
This chapter shows you how to:

- Navigate large models
- Combine existing models into an integrated model
Show module hierarchy preference

Often a large model has many layers of hierarchy. You can see the hierarchy depth of each module at the top of its Diagram window by setting a preference. Select Preferences from the Edit menu to display the Preferences dialog box.

If you check the Show module hierarchy box, the top of the active Diagram window displays one or more module node shapes to indicate its hierarchy depth.
The Outline window

The Outline window displays a listing of the nodes inside a model. It can also show the module hierarchy as an indented list of modules. It provides an easy way to orient yourself in a large model and to navigate within it.

Opening the Outline window
To open the Outline window, click the Outline button in the toolbar. The Outline window highlights the entry for the selected module or variable.

Opening details from an outline
To display a module’s Diagram window, double-click its entry in the outline. To display a variable’s Object window, double-click its entry in the outline.

Expanding and contracting the outline
By default, the outline lists all nodes in the model. Check the Modules Only box to list only the modules (exclude variables and functions).

Viewing and editing attributes
The Attribute panel at the bottom of the Outline window works just like the Attribute panel available at the bottom of a Diagram window (see “Diagram window” on page 17).
To view the attributes of a listed node:

1. Select the node by clicking it.
2. Choose the attribute to examine from the Attribute popup menu (see “Creating or editing a definition” on page 116).

If you edit attributes in this panel, the changes are propagated to any other Attribute panels and Object windows.

**Finding variables**

To locate a variable in its diagram, by identifier or by title, use the Find dialog box.

**Find dialog box**

To display the Find dialog box:

1. Select Find (Control+f) from the Object menu.

2. Choose the attribute to search by: Identifier or Title.

3. In the text field, enter the identifier or title for the Analytica object for which you want to search. You can enter an incomplete identifier or title, such as “down” for “Down payment.”

4. Click the Find button to initiate the search.
Managing attributes

Every node in an Analytica model is described by a collection of attributes. For some models, you may want to control the display of attributes or create new attributes. Some attributes apply to all classes (variable, module, and function). Others apply to specific classes, as listed in the following table.

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Function</th>
<th>Module</th>
<th>Variable</th>
</tr>
</thead>
<tbody>
<tr>
<td>Author</td>
<td></td>
<td>*</td>
<td></td>
</tr>
<tr>

<td>+</td>
<td>+</td>
<td>+</td>
</tr>
</tbody>
</table>

Key:
- plain = modifiable by user
- * = always displayed

The Diagram window containing the object found is displayed, with the node of the object selected.

If the name you type does not match completely any existing identifier or title (depending on which attribute you are searching), the first identifier or title that is a partial match will be displayed.

To find the next object that is a partial match to the last identifier or title that you entered, select Find Next (Control+g) from the Object menu.

To find an object whose identifier matches the selected text in an attribute field (such as a definition field), select Find Selection (Control+h) from the Object menu.
Managing attributes

Attributes dialog box

Use the Attributes dialog box to control the display of optional attributes in the Object window and Attribute panel and to define new attributes.

To open the Attributes dialog box, select Attributes from the Object menu.

- Class popup menu
  Use this menu to select the Attribute list for variables, modules, or functions.

- Attribute list
  This list shows attributes for the selected class. Attributes with an asterisk (*) are always displayed in the Object window and Attribute panel. Attributes with a check mark (√) are displayed optionally.

Displaying optional attributes

To display an optional attribute in the Object window and Attribute panel, click it once to select it, then click it again to show a check mark.

To hide an optional attribute, click it once to select it, then click it again to remove the check mark.

Creating new attributes

You can create up to five additional attributes. For example, you could use a reference attribute to include the bibliographic reference for a module or variable.

To create a new attribute in the Attributes dialog box:

1. Select new Attribute from the attribute list to show the new Attribute Title field and the Create button.
2. Enter the title for the new attribute in the Title field. The title can contain a maximum of 14 characters; 10 characters are the maximum recommended for visibility with all screen fonts.
3. Click the Create button to define the new attribute.

A newly created attribute is displayed for modules, variables, and functions. To control whether or not it is displayed for modules, variables, or functions, select the Class popup menu in the Attributes dialog box, and turn the check mark on or off.

Renaming an attribute

To rename a created attribute:

1. Select it in the Attribute list. The Title field and the Rename button appear.
2. Edit the name of the attribute in the Title field.
3. Click the Rename button.

Referring to the value of an attribute

Analytica includes the following function for referring to the value of an attribute in a variable’s definition:

**Attrib Of x**

Returns the value of attribute `attrib` of object `x`, where `x` may be a variable, function, or module. For most attributes, including `Identifier`, `Title`, `Description`, `Units`, `Definition`, and user-defined attributes the result is a text value. For `Value` and `Probvalue`, the result is the value of the variable (deterministic or probabilistic, respectively). For `Inputs`, `Outputs`, and `Contains` (an attribute of a module), the result is a vector of variables.

You cannot refer to an attribute of a variable by naming the variable in the definition of that variable. Instead, refer to it as `Self`, for example:

```plaintext
Variable Boiling_point
Units: F
Definition: If (Units of Self) = 'C'
    THEN 100 ELSE 212

Boiling_point \rightarrow 212
```

**Tip** Changes to attributes other than `Definition` do not automatically cause recomputation of the variables whose definitions refer to those attributes. So, if you change Units of `Boiling_point` to C, the value of `Boiling_point` will not change until `Boiling_point` is recomputed for some other reason.

Invalid variables

To locate all variables in a model with syntactically incorrect or missing definitions, select **Show Invalid Variables** from the **Definition** menu.
Double-click a variable to open its **Object** window. From the **Object** window, you can edit the definition, or click the **Parent Diagram** button to see the variable in its diagram.

### Using filed modules and libraries

Modules and libraries can be components of a model. If you are building several similar models, or if you are building a large model composed of similar components, you can create modules and libraries for reuse. (See Chapter 20, “Building Functions and Libraries” for details about libraries.)

To use a module or library in more than one model, create a **filed module** or **filed library**.

#### Creating a filed module or library

To create a filed module or library:

1. Create a module by dragging the module icon from the node palette onto the diagram, and give it a title.

2. Create functions and/or variables in the module, or create them elsewhere and move them into the module.

3. Change the class of the module to **Module** or **Library** (see “To change the class of an object” on page 58).

4. The **Save As** dialog box appears. Give the filed module or library a name and save it.

5. If you want the original model to load the new filed module or library the next time it is opened, save the model using the **Save** command.

#### Locking a filed module or library

To prevent a filed module or library from being modified, lock it:

1. Close the filed module or library, or close Analytica.

2. In Windows Explorer, select the filed module or library.

3. Select **Properties** from the **File** menu.
Chapter 19  Working with Large Models

Using figured modules and libraries

4. Check the **Read-only** check box.
5. Close the **Properties** window.

**Adding a module to a model**

To add a figured module to the active model, use the **Add Module** dialog box (see “Adding a module or library”). You can either embed a copy of the module or link to the original of the figured module.

**Adding library to a model**

To add a figured library to the active model, use the **Add Module** dialog box (see “Adding a module or library”). You can either embed a copy of the library or link to the original of the figured library.

When you select **Add Library** from the **File** menu, the **Open File** dialog box always opens up to figured directory, regardless of the current directory settings or previous changes of directories. The directory is determined by a registry setting: \Lumina\Decision Systems\Analytica\3.0\AddLibraryDir, which is set by the Analytica installer to INSTALLDIR/Libraries.

**Removing a module or library from a model**

To remove a figured module or library from a model, first select it. Then, select **Cut** or **Clear** from the **Edit** menu. An embedded copy will be deleted; a linked original will still exist as a separate file.

**Warning:** Any definitions that use a function in a deleted library or that have an input from a deleted module or library will have the deleted object removed and will be changed to **FunctionOf** *(remaining variables)*.
Adding a module or library

Use the Add Module dialog box to add a filed module or library to the active model.

If you are adding a module, you open the Add Module dialog box by selecting Add Module from the File menu (Control+l). If you are adding a library, you open the Add Module dialog box by selecting Add Library from the File menu.

The standard Open Model dialog box appears. Select the desired module in that dialog box. The following dialog box then appears:

Tip
Be sure that the selected model or module was saved with a class of filed module or filed library. If it was saved with a class of model, when it is linked to the root model, its preferences and uncertainty settings will overwrite the preferences and uncertainty settings of the root model.

An added module or library may be either embedded or linked. You can optionally overwrite any nodes with the same identifiers.

Embed a copy
Embeds a copy of the selected module or library in the active model, making it a part of, and saving it with, the model. Any changes to the copy will not affect the original filed module or library.

Link to original
Creates a link to the selected module or library, which can be separately opened and saved. If you make changes to a linked module or library from one model, the changes are saved in the original's file and any other models linked to the original will be affected by the changes.

A linked module or linked library has a bold arrow pointing into it on the diagram.
Combining models into an integrated model

Large models introduce a unique set of modeling issues. Modelers may want to work on different parts of a model simultaneously, or at remote locations. During construction, a large model may be more tractable when broken into modular pieces (modules), but all modules should use a common set of indexes and functions. Analytica provides the functionality required to support large-scale, distributed modeling efforts.

This section describes how to best use Analytica for large modeling projects and contains suggestions for planning a large model where responsibility for each module is assigned to different people (or teams).

Define public variables

The first step to creating an integrated model is to define public variables for use by all modules and agree on module linkages.

Every integrated model will have variables that are used by two or more projects (for example, geographical, organizational, or other indexes, modeling parameters, and universal constants). These public variables should be defined in a separate module, and distributed to all project teams. Each team uses Add Module (see “Adding a module or library”) to add the public variables module to its model at the outset of modeling. Using a common module for public variables avoids duplication of variables and facilitates the modules’ integration.

Source control over the public variable module must be established at the outset so that all teams are always working with the same public variables module. Modelers should not add, delete, or change variables in the public variables module unless they inform the source controller, who can then distribute a new version to all modelers.

If multiple teams will be working on separate projects, it is essential that the teams agree upon inputs and outputs. Modelers must specify the input variables, units, and dimensions that they are expecting as well as the output variables, units, and dimensions that they will be providing. The indexes of these inputs and outputs should be contained in the public variables module.

Merge contents (overwrite)

Select this check box to overwrite existing objects in the active model with objects with the same identifiers from the added module or library. This is useful if the file being added contains updates from a previous version.

If you do not select this check box, and an object in the file being added has the same identifier as one in the active model, Analytica will point that out and ask if you want to rename the variable. If you click Yes, it will rename the variable in the existing model, and update all definitions in the existing model to use the changed identifier. It will leave unchanged the identifier of the variable in the module it is adding (which may contain definitions referencing that identifier that it has yet to read.) Hence, all the definitions in the existing model and added module will continue to reference the correct (original) variables.
Create a modular model

By keeping large pieces of a model in separate, or filed modules, modelers can work on different parts of a model simultaneously. You can break an existing model into modules, or combine modules into an integrated model. In both cases, the result is a top-level model, into which the modules are added.

To save pieces of a large model as a set of filed modules, see “Using filed modules and libraries”.

To combine existing models into a new, integrated model:

1. Create or open the model that will be the top level of the hierarchy. This is the model to which all sub-models will be added.

2. Using Add Module (see “Adding a module or library”), add in the sub-models. Be sure to check the Merge option in the Add Module dialog box. Add the modules in the following sequence:
   - Any public variable modules
   - All remaining modules in order of back to front; that is:
     - first, the module(s) whose outputs are not used by any other module, and
     - last, the module(s) which take no inputs from any other module.

3. Save the entire integrated model, using the Save command.

The two alternative methods of controlling each module’s input and output nodes so the modules can be easily integrated, are:

- Identical identifiers
- Redundant nodes

Identical identifiers

Assign the input nodes in each module the exact same identifiers as the output nodes in other modules that will be feeding into them. When you add the modules beginning with the last modules first (that is, those at the end of model flow diagram), the input nodes will be overwritten by the output nodes, thus linking the modules and avoiding duplication.

With identical identifiers, the individual modules cannot be evaluated alone because they are missing their input data. They can be evaluated only as part of the integrated model.

Redundant nodes

Place the output node identifiers in the definition fields of their respective input nodes. Due to the node redundancy, this method requires more memory than using identical identifiers, and it is therefore less desirable when large tables of data are passed between modules. However, since no nodes are overwritten and lost upon integration, this method preserves the modules’ structural integrity, with both input and output nodes visible in each module’s diagram.

With redundant nodes, each module can be opened and evaluated alone, using stand alone shells.

Stand alone shells

With redundant nodes, you can create a top-level model that contains one or more modules and the public variables module plus dummy inputs and outputs. Such a top-level model is called a stand alone shell because it allows you to open and evaluate a single module “standing alone” from the rest of the integrated model. Stand alone shells are useful when modelers want to examine or refine a particular module without the overhead of opening and running the entire model.

To create a stand alone shell for module Mod1, which is a filed module:
1. Open the integrated model and evaluate all nodes that feed inputs to Mod1.

2. Use the Export command (see “Importing and exporting”) to save the value of each feeding node in a separate file. Make a note of:
   - The identifier of each node and the indexes by which its results are dimensioned,
   - The identifiers of Mod1’s output nodes, if you want to include their dummies in the stand alone shell.

3. Close the integrated model.

4. Create a new model, to be the stand alone shell.

5. Use Add Module to add the public variables module.

6. For each input node, create a node containing an edit table, using the identifier and dimensions of the feeding nodes you noted from the integrated model.

7. Use the Import command (see “Importing and exporting”) to load the appropriate data into each node’s edit table.

8. Use Add Module to add Mod1 into the stand alone shell.

9. To include output nodes at the top level of the hierarchy, create nodes there and define them as the identifiers of Mod1’s outputs.

10. Save the shell.

The shell now has all the components necessary to open and evaluate Mod1, without loading the entire model. As long as modelers do not make changes to the dimensions or identifiers of module inputs and outputs, they can modify a module while using the stand alone shell, and the resulting module will be usable within the integrated model.

Cautions in combining models

**Identifiers**
Every object in a model must have a unique identifier. The identifiers of filed libraries and filed modules that you add to a model, as well as their variables and functions, cannot duplicate identifiers in the root model. See "Merge contents (overwrite)."

**Created attributes**
When you combine models with created attributes, the maximum number of defined attributes is five (see "Managing attributes").

**Location of linked modules and libraries**
If the model will eventually be distributed to other computers, all modules and libraries should be on the same drive as the root model prior to being added to the root model. When the model is distributed, distribute it with all linked modules and libraries.

Managing windows

An Analytica model can potentially display thousands of Diagram, Object, and Result windows. To prevent your screen from becoming cluttered, Analytica limits the number of windows of each type that can be open at once. The default limits are:

- The top-level Diagram window and not more than one Diagram window for each lower level in the hierarchy
- One Object window
Optimization and speed-up

Numerous optimizations in the Analytica 3.1 engine result in a substantial increase in speed over Analytica 2.0. We have found a factor of between 1.5 and 4 reduction in the time to evaluate a model, depending on the functions and dimensionality of the model.

One example improvement is in \texttt{Subscript()}. For example, the evaluation of \( A[I=J] \), or equivalently \texttt{Subscript(A, I, J)}, is now approximately linear in the size of \( J \), rather than proportional to the product of the sizes of \( I \) and \( J \), as it used to be.

Rectangularization of intermediate results

In the most general case, intelligent array abstraction requires an extra internal, but somewhat costly, step during evaluation to make sure all intermediate arrays are fully rectangular. Skipping this step seldom has an impact on the final result, but can speed things up dramatically for certain models, especially those using dynamic simulation extensively. Unfortunately, in the very rare cases where it does make a difference, skipping the step can lead in incorrect results. By default, Analytica 3.1 uses the safe but slower setting, for the system variable, \texttt{Rectangularize_inter}, that controls this. You can clear this setting in the Preferences window for faster execution. See “Safe Intermediates”.

Overriding the limits on the number of windows

To display more windows of the same type, override the default limits in one of the following ways:

- Open a second Object window, or open a Diagram window without closing an existing Diagram window at the same level, by pressing the Control key (\texttt{Control}) while you click or double-click to open the new window.
- Use the Preferences dialog box (see “Preferences dialog”) to change the limits. Select Preferences from the Edit menu.

In the Windows of each Kind area, select Any number instead of One only.

To display more Result windows and keep the limit on Diagram and Object windows, enter the maximum number of Result windows.
Building Functions and Libraries

This chapter shows you how to:
• Create your own functions
• Create your own function libraries
Building Functions and Libraries

You can create your own functions to perform calculations you use frequently. A function has one or more parameters; its definition is an expression that uses these parameters. You can specify that the function check the type or dimensions of its parameters, and control their evaluation by using various parameter qualifiers.

A library is a collection of functions grouped in a library file to extend Analytica’s built-in functions for use for particular types of application, more than one model. Analytica is distributed with an initial set of libraries, available in the Libraries folder inside the Analytica folder on your hard disk. If you add a library to a model, it will appear with its functions in the Definition menu, and these functions will appear almost the same as the built-in functions.

You may want to look at these libraries to see if they provide functions useful for your applications. You may also look at library functions as a starting point or inspiration for writing your own functions.

Analytica experts may create their own function libraries for particular domains. Other Analytica users can benefit from these libraries.

Example function

The following function, Capm(), computes the expected return for a stock under the capital asset pricing model.

Parameters  The three parameters, Rf, Rm, and Beta, are qualified to be numbers.
Definition   The definition is a simple expression using Rf, Rm, and Beta.
Sample usage You use the Capm() function in a definition in the same way you would use Analytica’s built-in functions. For example, if the risk free rate is 5%, the expected market return is 8%, and StockBeta is defined as the beta value for a given stock, we can find the expected return according to the capital asset pricing model as:

\[
\text{Expected Return} = \text{Rf} + \text{Beta} \times (\text{Rm} - \text{Rf})
\]
Using a function

**Position-based calling syntax**

Analytica uses the standard *position-based syntax* for using, or calling, a function. You simply list the actual parameters after the function name, within parentheses, and separated by commas, in the same sequence in which they are defined. For example,

\[
\text{Capm}(5\%, 8\%, \text{StockBeta})
\]

evaluates function \(\text{Capm}(\text{Rf}, \text{Rm}, \text{Beta})\) with \(\text{Rf}\) set to 5\%, \(\text{Rm}\) set to 8\%, and \(\text{Beta}\) set to \(\text{StockBeta}\).

**Name-based calling syntax**

Analytica also supports a much more flexible *name-based calling syntax*, using the names of the parameters:

\[
\text{Capm}(\text{beta}: \text{StockBeta}, \text{rf}: 5\%, \text{rm}: 8\%)
\]

In this case, we name each parameter, and put its actual value after a colon "::" after the parameter name. The name-value pairs are separated by commas ",". The parameters can be specified in any order, provided all the required parameters are mentioned. This method is much easier to read when the function has many parameters. It is especially useful when there are many parameters and some are optional. See “Optional parameters” for how to qualify parameters as optional.

You can mix positional and named parameters, as in:

\[
\text{Fu1}(1, 2, D:4, C:3)
\]

But, you may not list a positional parameter after a named parameter:

\[
\text{Fu1}(1, D:4, 2, 3)
\]

will display an error message.

This *name-based calling syntax* is analogous to Analytica’s *name-based subscripting* for arrays to obtain selected elements of an array. In each case, you do not need to remember the particular sequence of parameters or indexes to understand how the model works.

**Tip**

Name-based calling syntax works for all user-defined functions. It also works for some of the built-in functions, including the Financial library, text functions, Optimizer functions, \(\text{EigenDecomp}\), and \(\text{MatrixMultiply}\). We recommend that you do not use it for other built-in functions.

Creating a function

To define a function:

1. Make sure the edit tool is selected and you can see the node palette.
2. Drag the **Function node** icon from the node palette into the diagram area.
3. Title the node, and double-click it to open its Object window.
4. Enter the new function’s attributes (described in the next section).

Attributes of a function

Like other objects, a function is defined by a set of attributes. Many of these attributes are the same as the attributes of variables, including identifier, title, units, description, and definition, inputs, and outputs. It possesses one unique attribute, Parameters, which specifies the parameters available to the function.

Identifier
If you are creating a library of functions, make a descriptive identifier. This identifier appears in the function list for the library under the Definition menu, and is used to call the function. Analytica makes all characters except the first one lower case.

Title
If you are creating a library of functions, limit the title to 22 characters. This title appears in the Object Finder dialog box to the right of the function.

Units
If desired, use the units field to document the units of the function’s result. The units are not used in any calculation.

Parameters
The parameters to be passed to the function must be enclosed in parentheses, separated by commas. For example: \((x,y,z)\)

The parameters may have type qualifiers (see the next section).

If you are creating a library of functions, use descriptive abbreviations for the parameters and give them a logical sequence. The parameters will appear in the Object Finder dialog box and they will be pasted when the function is pasted from its library in the Definition menu.

Description
The description should first document what the function returns, and explain each of its parameters. If the definition is not immediately obvious, the second part of the description should explain how it works. The description text for a function in a library also appears in a scrolling box in the bottom half of the Object Finder dialog.

Definition
The definition of a function is an expression or compound list of expressions. It should use all of its parameters. When you select the definition field of a function in edit mode, it shows the Inputs pull-down menu that lists the parameters as well as any other variables or functions that have been specified as inputs to the function. You can specify the inputs to a function in the same way as for a variable, by drawing arrows from each input node into the function node.

Parameter qualifiers

Parameter qualifiers are keywords you may use in parameters to specify for each parameter how, or whether, it should be evaluated when the function is used (called), and whether it should have a particular type of value, such as number, text value, or other. Other qualifiers specify whether a parameter should be an array, and if so, which indexes it expects. You can also specify whether a parameter is optional. By using qualifiers properly, you can help make functions easier to use, more flexible, and more reliable.

For example, consider this parameters attribute:
(A: Number Array[I,J]; I, J: Index; C; D: Optional Atom Text)

It defines five parameters, A, I, J, C, and D. A should be an array of numbers, indexed by parameters I and J. I and J, being separated by commas ",," rather than semicolons ";" are subject to the same qualifier, Index. C has no qualifiers, and so can be of any type, or dimensions. The semicolon ";" between C and D means that the qualifiers following D do not apply to C. D has three qualifiers, specifying that it is Optional, Atom, and a text value. See below for details.

Evaluation mode qualifiers

Evaluation modes control how, or whether, Analytica evaluates each parameter when a function is used (called). The evaluation mode qualifiers are:

**Context**
Evaluates the parameter deterministically or probabilistically according to the current context. For example, consider

Function Fnl(x)

Parameters: (x: Context)

Mean(Fnl(x))

Mean() is a statistical function that always evaluates its parameter probabilistically. Hence, the evaluation context for x is probabilistic, and so Fnl will evaluate x probabilistically.

**Context** is the default evaluation mode used when no evaluation mode qualifier is mentioned. So, strictly, **Context** is redundant, and you can omit it. But, it is sometimes useful to specify it explicitly to make clear that the function should be able to handle the parameter whether it is deterministic or probabilistic.

**ContextSample**
Causes the qualified parameter to be evaluated in prob mode if any of the other parameters to the function are Run. If not, it evaluates in context mode — i.e., prob or mid following the context in which the function is called.

This qualifier is used for the main parameter of most built-in statistical functions. For example, Mean has these parameters:

Mean(x: ContextSample[i]; i: Index = Run)

Thus, Mean(X, Run) evaluates X in prob mode. So does Mean(X), because the index i defaults to Run. But, Mean(X, J) evaluates X in mid mode, because J is not Run.

When the parameter declaration contains more than one dimension, prob mode is used if any of the indexes is Run.

**Mid**
Evaluates the parameter deterministically, or in mid mode, using the mid (usually median) of any explicit probability distribution.

**Prob**
Evaluates the parameter probabilistically, i.e., in prob mode, if it can. If you declare the dimension of the parameter, include the dimension Run in the declaration if you want the variable to hold the full sample, or omit Run from the list if you want the variable to hold individual samples. For example:

( A : Prob [ In1, Run ] )

**Sample**
Evaluates the parameter probabilistically, i.e., in prob mode, if it can. If you declare the dimension of the parameter, include the dimension Run in the declaration if you want the
variable to hold the full sample, or omit Run from the list if you want the variable to hold individual samples. For example:

\[( A : \text{Sample[ In1, Run ]})\]

**Index** The parameter must be an index variable, or a dot-operator expression, such as \(A.I\). You can then use the parameter as a local index within the function definition. This is useful if you want to use the index in a function that requires an index, for example \(\text{Sum}(X, I)\) within the function.

**Variable** The parameter must be a variable, or the identifier of some other object. You can then treat the parameter name as equivalent to the variable, or other object name, within the function definition. This is useful if you want to use the variable in one of the few expressions or built-in functions that require a variable as a parameter, for example, \(\text{WhatIf}\), \(\text{DyDx}\), and \(\text{Elasticity}\).

**Array qualifiers**

An array qualifier can specify that a parameter is an array with specified index(es) or no indexes, in the case of \(\text{Scalar}\).

**Scalar** The parameter expects a single number, not an array. Means the same as \(\text{Number Atom}\).

**Atom** If the actual parameter is an array, the function is called separately on each atomic element of the array. The results of all the calls to the function are reassembled into an array with the same indexes as the original parameter, which is returned as the overall result.

You might be tempted to use \(\text{Atom}\) to qualify parameters of every function, just in case. Functions with \(\text{Atom}\) parameters may take longer to execute because they have to do all that disassembly of the array-valued parameters, multiple evaluations, and reassembly of the results. So, avoid using it in time-consuming functions except when really necessary.

**Array** Dimensionality declaration, when present, forces Analytica to perform horizontal array abstraction over the parameters when additional dimensions are present. For example, if \(F1\) has the parameter declaration:

\[(A: \text{Array[Time]})\]

and if \(A\), when evaluated, contains dimensions other than Time, Analytica will loop over the other dimensions, ensuring that within the function \(A\) contains no dimension other than Time.

A dimensionality declaration usually the following the form:

\[\text{Array [ In1, In2, ... ]}\]

Zero or more indexes can be specified between the square brackets. A zero-index declaration means that the value will be an atom when the function body is evaluated, and in this case the keyword \(\text{Atom}\) may be used. \(\text{Array}\) is also optional (e.g., one could write \(\text{Number [In1]}\) rather than \(\text{Number Array [In1]}\).

Each index identifier listed inside the brackets may be either a global index variable or another parameter explicitly qualified as an Index. For example the \(\text{Parameters}\) attribute:

\[(A: [\text{Time, J}]; J: \text{Index})\]
specifies that parameter A must be an array indexed by time (a built-in index variable) and by the index variable passed to parameter J.

In the absence of an array qualifier, Analytica accepts an array-valued parameter for the function, and passes it into the function Definition for evaluation with all its dimensions (indexes). This kind of vertical array abstraction is usually more efficient for those functions that can handle array-valued parameters.

**All** Forces the parameter to have or be expanded to have all the Indexes listed. For example, in

\[ X: \text{All} [I, J] \]

the `All` qualifier forces the value of \( x \) to be an array indexed by the specified index variables, \( I \) and \( J \). If \( x \) is a single number, not an array, **All** forces Analytica to convert it into an array with indexes, \( I \) and \( J \), repeating the value of \( x \) in each element. Without **All** Analytica would simply pass the scalar value \( x \) into the function definition.

### Type checking qualifiers

**Type checking qualifiers** make Analytica check whether the value of a parameter (each element of an array-valued parameter) has the expected type — such as, numerical, text, or reference. If any values do not have the expected type, Analytica gives an evaluation error at the time it tries to use (call) the function. The type checking qualifiers are:

- **Number** A number, including \(+\text{INF}\), \(-\text{INF}\), or \(\text{NaN}\).
- **Positive** A number greater than zero, or \(\text{INF}\).
- **Nonnegative** Zero, or a number greater than zero or \(\text{INF}\).
- **Text** A text value.
- **Reference** A reference to a value, created with the `\` operator.
- **Unevaluated**

If you accompany a Type checking qualifier by the **Coerce** qualifier, it will try to convert, or coerce, the value of the parameter to the specified type. For example:

\[ A: \text{Coerce} \text{Text} [I] \]

will try to convert the value of \( A \) to an array of text values. It will give an error message if any of the coercions are unsuccessful.

If the conversion cannot occur, an error is issued. The following coercions are allowed:

- **Undef** to text (blank)
- **Null** to text ("Null")
- **Number** to text (uses number format for caller)
- **Text** to **Positive** (date vs. number based on number format)
- **Text** to **Number** (date vs. number based on number format)
- **Undef** to **Reference** (\Undefined)
- **Null** to **Reference** (\Null)
- **Number** to **Reference** (\X)
- **Text** to **Reference** (\Text)
Other coercions, including `Undef` or `Null` to `Number` or `Positive` will result in an error that the coercion is not possible.

**Ordering qualifiers**

The ordering qualifiers, `Ascending` or `Descending`, check that the parameter value consists of numbers in the specified order. Ordering also works for text values. `Ascending` means alphabetical order, and `Descending` means the reverse.

Ordering is not strict: That is, it allows successive elements to be the same. For example, `[1,2,3,3,4]` and `[‘Anne’, ‘Bob’, ‘Bob’, ‘Carmen’]` are both considered ascending.

If the value of the parameter does not have the specified ordering, or it is an atom (not array) value, Analytica will issue an evaluation error when trying to evaluate the function call.

If the parameter has more than one dimension (other than `Run`), you should specify the index of the dimension over which to check the order, thus:

```
A : Ascending [I]
```

**Optional parameters**

Any parameter may be optional if declared as optional by including the keyword `Optional`, within the declaration. Optional parameters may appear anywhere within the declaration — they are not limited to the final parameters. So, for example, one could declare the parameters for `Fu1` as

```
(A: Optional; B; C: Optional; D; E: Optional)
```

To call `Fu1`, you could use any of these examples:

```
Fu1(1,2,3,4,5)
Fu1(1,2,,4)
Fu1(,,2,,4)
Fu1(,,2,3,4,5)
```

Or you could use named-based calling syntax:

```
Fu1(B:2, D:4)
```

which is clearer and simpler.

When a middle parameter is omitted, an empty space between commas must be included when the function is called. If all parameters following the last parameter provided are optional, placeholder commas are not necessary.

When a parameter is omitted, the value will have a special internal value such as `undefined` (or a different internal value if a variable is omitted). You can detect this inside the function definition using function `IsNotSpecified`. For example, the first line of the body of the function might read:

```
If IsNotSpecified(A) then A := 0;
```

Take care with omitted variable and Index parameters. Some built-in functions may crash if passed an unspecified `Index` or `Variable` parameter.

If a function with an omitted parameter value passes it as a parameter to a second function whose parameter is not optional, it displays a warning message. For example:

Fu1(A : optional) := Fu2(A)
Fu2(B) := B
Va1 := Fu1()

will display the message

Error: Parameter B is not optional in function Fu2.

**Deprecated synonyms for parameter qualifiers**

Most parameter qualifiers have several synonyms. For example, Atomic, AtomType, and AtomicType are synonyms for Atom. We recommend that you use only the words listed above. If you encounter other synonyms in older models, consult the Analytica wiki "Deprecated qualifiers" to see what they mean (http://lumina.com/wiki/).

**Libraries**

When you place functions and variables in a library, the library becomes available as an extension to the system libraries. Its functions and variables also become available. Up to eight user libraries can be used in a model.

There are two types of user libraries (see also “To change the class of an object” on page 58):

- A library is a module within the current model.
- A filed library is saved in a separate file, and can be shared among several models.

**Creating a library**

To create a library of functions and/or variables:

1. Create a module by dragging the module icon from the node palette onto the diagram, and give it a title.
2. Change the class of the module to library or filed library (see “To change the class of an object” on page 58).
3. Create functions and/or variables in the new library or create them elsewhere in the model and then move them into the library.

Functions and variables in the top level of the library can be accessed from the Definition menu or Object Finder. Use modules within the library to hold functions and variables (such as test cases) that will not be accessible to models using the library.

**Adding a filed library to a model**

Add a filed library to a model using the Add Module dialog box (see "Adding a module or library").
Using a library

When defining a variable, you can use a function or variable from a library in any of the following ways:

- Type it in.
- Select Paste Identifier from the Definition menu to open the Object Finder.
- Select Other from the Expression popup menu to open the Object Finder.
- Paste from the library under the Definition menu.

Example  
Compare the way the \texttt{Capm()} function is displayed in the Object window (page 345) to the way it is displayed in the Object Finder:
Chapter 21

Procedural Programming

This chapter shows you how to use the procedural features of the Analytica modeling language.
A procedural program is sequence of instructions to a computer. Each instruction tells the computer what to do, or in what sequence to execute the instructions. Most Analytica models are non-procedural — that is, they consist of an unsequenced set of definitions of variables. Each definition is a simple expression that contain functions, operators, constants, and other variables, but no procedural constructs controlling the sequence of execution. In this way, Analytica is like a standard spreadsheet application, in which each cell contains a simple formula with no procedural constructs. Analytica determines the sequence in which to evaluate variables based on the dependencies among them, somewhat in the same way spreadsheets determine the sequence to evaluate their cells. Non-procedural languages free you from having to think about it. Non-procedural models or programs are easier to write and understand because you can understand each definition (or formula) without worrying about the sequence of execution. Procedural programs, such as most programs in Fortran, Visual Basic, or C++, are much harder to write and understand.

However, procedural languages enable you to write more powerful functions that are hard or impossible without their procedural constructs. For this reason, Analytica 3.0 introduced a set of such constructs, providing a general procedural programming language for those who want it. Together, these constructs provide much greater power and flexibility for creating definitions, and especially, for defining new functions in Analytica.

These constructs may only be used within the definition of a variable or function to control the flow of execution within that variable or function. They cannot affect other variables or functions directly, and do not affect the flow of execution in other variables or functions. Thus, the availability of these constructs does not affect the simple nonprocedural relationship among variables and functions.

An example of procedural programming

The following function, Factors(), computes the prime factors of an integer x. It illustrates many of the key constructs of procedural programming.
Chapter 21  Procedural Programming

See below for an explanation of each of these constructs, and cross-reference to where they are.

**Function Factors(x)**

**Definition:**

1. \( \text{VAR result} := [1] \);
2. \( \text{VAR } n := 2 \);
3. \( \text{WHILE } n \leq x \text{ DO} \)
4. \( \text{BEGIN} \)
2. \( \text{VAR } r := \text{Floor}(x/n); \)
   IF \( r \times n = x \) THEN
5. \( \text{(result := Concat(result, [n]);} \)
6. \( x := r) \)
   ELSE \( n := n + 1 \)
4, 7. \( \text{END; /* End While loop */} \)
7, 8. \( \text{result} /* End Definition */ \)

This definition illustrates these features:

1. \( \text{VAR x := e} \) construct defines a local variable \( x \), and sets an initial value \( e \). See page 351 for more.
2. You can group several expressions (statements) into a definition by separating them by `;` (semicolons). Expressions can be on the same line or successive lines. See page 350.
3. **While test Do body** construct tests condition **Test**, and, if True, evaluates **Body**, and repeats until condition **Test** is False. See page 355.
4. **Begin \( e1; e2; \ldots \) End** groups several expressions separated by `;`’s — in this case as the body of a While loop. See page 350.
5. \( (e1; e2; \ldots) \) is another way to group expressions — in this case, as the action to be taken in the Then case. See page 350.
6. \( x := e \) lets you assign the value of an expression \( e \) to a local variable \( x \) or, as in the first case, to a parameter of a function. See page 351.
7. A comment is enclosed between `/*` and `*/` as an alternative to `{ and }.
8. A group of expressions returns the value of the last expression — here the function **Factors** returns the value of **result** — whether the group is delimited by **Begin** and **End**, by `(` `and ` `)`, or, as here, by nothing.
Summary of programming constructs

Begin-End, ( ), and ’;’ for grouping expressions

As illustrated above, you can group several expressions (statements) as the definition of a variable or function simply by separating them by ’;’s (semicolons). To group several expressions as a condition or action of If a Then b Else c or While a Do b, or, indeed, anywhere a single expression is valid, you should enclose the expressions between Begin and End, or between ‘(’ and ‘)’.

The overall value of the group of statements is the value from evaluating the last expression. For example:

\[
(VAR x := 10; x := x/2; x - 2) \rightarrow 3
\]
Analytica will also tolerate a ';' after the last expression in a group. It still returns the value of the last expression. For example:

\[(\text{VAR } x := 10; x := x/2; x/2; ) \to 2.5\]

The statements can be grouped on one line, or over several lines. In fact, Analytica does not care where new-lines, spaces, or tabs occur within an expression or sequence of expressions — as long as they are not within a number or identifier.

### Declaring local variables and assigning to them

#### Defining a local variable: \( \text{Var } v := e \)

This construct creates a local variable \( v \) and initializes it with the value from evaluating expression \( e \). You can then use \( v \) in subsequent expressions within this context — that is, in following expressions in this group, or nested within expressions in this group. You cannot refer to a local variable outside its context — for example, in the definition of another variable or function.

If \( v \) has the same identifier (name) as a global variable, any subsequent mention of \( v \) in this context refers to the just-defined local variable, not the global.

**Examples**

Instead of defining a variable as:

\[
\text{Sum(Array_a*Array_b,N)/(1+Sum(Array_a*Array_b,N))}
\]

define it as:

\[
\text{VAR t := Sum(Array_a*Array\_b, N); t/(1+t)}
\]

To compute a correlation between \( Xdata \) and \( Ydata \), instead of:

\[
\text{Sum((Xdata-Sum(Xdata,Data\_index)/Nopts)*(Ydata-Sum(Ydata,Data\_index)/Nopts),Data\_index)/ Sqrt(Sum((Xdata-Sum(Xdata,Data\_index)/Nopts)^2, Data\_index) * Sum((Ydata - Sum(Ydata,Data\_index)/Nopts)^2,Data\_index))}
\]

define the correlation as:

\[
\text{VAR mx := Sum(Xdata, Data\_index)/Nopts;}
\]
\[
\text{VAR my := Sum(Ydata, Data\_index)/Nopts;}
\]
\[
\text{VAR dx := Xdata - mx;}
\]
\[
\text{VAR dy := Ydata - my;}
\]
\[
\text{Sum(dx*dy,Data\_index)/Sqrt(Sum(dx^2, Data\_index)*Sum(dy^2, Data\_index))}
\]

The latter expression is faster to execute and easier to read.

The correlation expression in this example is an alternative to Analytica's built-in \texttt{Correlation()} function (see "Correlation(x, y)" on page 278) when data is dimensioned by an index other than the system index \texttt{Run}.

#### Assigning to a local variable: \( v := e \)

The ':=' (assignment operator) sets the local variable \( v \) to the value of expression \( e \).
The assignment expression also returns the value of \( e \), although it is usually the effect of the assignment that is of primary interest.

The equal sign, '=' does not do assignment. It tests for equality between two values.

Within the definition of a function, you can also assign a new value to any parameter. This will change only the parameter and will not affect any global variables used as actual parameters in the call to the function.

**Tip** Usually, **you cannot assign to a global variable** — that is, to a variable created as a diagram node. You can assign only to a local variable, declared in this definition using `Var` or `Index`, in the current context — that is, at the same or enclosing level in this definition. In a function definition, you may also assign to a parameter. This prevents side effects — i.e., where evaluating a global variable or function changes a global variable, other than one that mentions this variable or function in its definition. Analytica’s lack of side effects makes models much easier to write, understand, and debug than normal computer languages that allow side effects: You can tell how a variable is computed just by looking at its definition, without having to worry about parts of the model not mentioned in the definition. There is an exception to this rule of no assignments to globals: You may assign to globals in button scripts or functions called from button scripts. See “Creating buttons and scripts” for details.

### Assigning to a slice of a local variable

**Slice assignment** means assigning a value into an element or slice of an array contained by a local variable, for example:

\[
x[I = n] := e
\]

\( x \) must be a local variable, \( I \) is an index (local or global), \( n \) is a single value of \( I \), and \( e \) is any expression. If \( x \) was not array or was an array not indexed by \( I \), the slice assignment adds \( I \) as a dimension of \( x \).

You can write some algorithms much more easily and efficiently using slice assignment. For example:

```plaintext
Function Fibonacci_series(f1, f2, n: Number Atom) :=
    INDEX m := 1..n;
    VAR result := 0;
    result[m = 1] := f1;
    result[m = 2] := f2;
    FOR I := 3..n DO result[m = I] := result[m = I - 1] + result[m = I - 2];
    result
```

In the first slice assignment:

\[
result[m = 1] := f1;
\]

\( result \) was not previously indexed by \( m \). So the assignment adds the index \( m \) to result, making it into an array with value \( f1 \) for \( m=1 \) and its original value, 0, for all other values of \( m \).

More generally, in a slice assignment:

\[
x[I = n] := e
\]
If \( x \) was already indexed by \( I \), it sets \( x[I=n] \) to the value of \( e \). For other values of \( I \), \( v \) retains its previous value. If \( x \) was not already indexed by \( I \), the assignment adds \( I \) as a dimension of \( x \), and sets the slice \( x[I=n] \) to \( e \). All other slices of \( x \) over \( I \) retain their previous values. If \( x \) was indexed by other indexes, say \( j \), the result is indexed by \( I \) and \( j \). The assigned slice \( x[I=n] \) has the value \( e \) for all values of the other index(es) \( j \). Again, slices for other values of \( I \) retain their original values of \( x \).

You may index by position as well as name in a slice assignment, for example:

\[
x[@I = 2] := e
\]

assigns the value of \( e \) as the second slice of \( x \) over index \( I \).

Slice assignment, e.g., \( x[I = A] := e \), has three limitations:

- \( x \) must be a local variable.
- \( n \) must be an atom, not an array.
- You may use only one index. For example, you may not use an expression like \( x[I = A, J=B] := e \), with two index expressions. If \( x \) has two (or more) dimensions, you can create and assign a slice (e.g., a row) to \( x \).

### For and While loops and recursion

**Tip** Analytica’s Intelligent Array features means that you rarely need explicit iteration using FOR loops to repeat operations over each dimensions of an array, often used in conventional computer language. If you find yourself using FOR loops a lot in Analytica, this may be a sign that you are not using the Intelligent Arrays effectively. If so, please (re)read the section on Intelligent Arrays (see ).

#### For \( i := a \) Do expr

The **For** loop successively assigns the next atom from array \( a \) to local index \( i \), and evaluates expression \( expr \). \( expr \) may refer to \( i \), for example to slice out a particular element of an array. \( a \) may be a list of values defined by \( m..n \) or \( \text{Sequence}(m, n, \ dx) \) or it may be a multidimensional array. Normally, it evaluates the body \( expr \) once for each atom in \( a \).

The result of the **For** is an array with all the indexes of \( a \) containing the values of each evaluation of \( expr \). If any or all evaluations of \( expr \) have any additional index(es), they will also be indexes of the result.

Usually, the Intelligent Array features take care of iterating over indexes of arrays without the need for explicit looping. **For** is sometimes useful in these specialized cases:

- To avoid selected evaluations of \( expr \) that may be invalid or out of range, and can be prevented by nesting an `If-Then-Else` inside a **For**.
- To apply an Analytica function that requires an atom or one- or two-dimensional array input to a higher-dimensioned array.
- To reduce the memory needed for calculations with very large arrays by reducing the memory requirement for intermediate results.

See below for an example of each of these three cases.
Avoiding out-of-range errors

Consider the following expression:

\[
\text{If } X < 0 \text{ Then } 0 \text{ Else } \sqrt{X}
\]

The **If-Then-Else** is included in this expression to avoid the warning “Square root of a negative number.” However, if \( x \) is an array of values, this expression may not avoid the warning since \( \sqrt{X} \) is evaluated before **If-Then-Else** selects which elements of \( \sqrt{X} \) to include. To avoid the warning (assuming \( x \) is indexed by \( I \)) the expression can be rewritten as

\[
\text{For } j := I \text{ do}
\]

\[
\text{If } x[I=j] < 0 \text{ then } 0 \text{ else } \sqrt{x[I=j]}
\]

or as (see next section):

\[
\text{Using } y := x \text{ in } I \text{ do}
\]

\[
\text{If } y < 0 \text{ Then } 0 \text{ else } \sqrt{y}
\]

Situations like this can often occur during slicing operations. For example, to shift \( x \) one position to the right along \( I \), the following expression would encounter an error:

\[
\text{if } I < 2 \text{ then } x[I=1] \text{ else } x[I=I-1]
\]

The error occurs when \( x[I=I-1] \) is evaluated since the value corresponding to \( I-1=0 \) is out-of-range. The avoid the error, the expression can be rewritten as:

\[
\text{For } j := I \text{ do}
\]

\[
\text{If } j < 2 \text{ then } x[I=1] \text{ else } x[I=j-1]
\]

Out-of-range errors can also be avoided without using **For** by placing the conditional inside an argument. For example, the two examples above can be written without **For** as follows:

\[
\sqrt{\text{if } x < 0 \text{ then } 0 \text{ else } x}
\]

\[
x[I=\text{if } I < 2 \text{ then } 1 \text{ else } I-1]
\]

Dimensionality reduction

**For** can be used to apply a function that requires an atom, one- or two-dimensional input to a multi-dimensional result. This usage is rare in Analytica since array abstraction normally does this automatically; however, the need occasionally arises in some circumstances.

Suppose you have an array \( A \) indexed by \( I \), and you wish to apply a function \( f(x) \) to each element of \( A \) along \( I \). In a conventional programming language, this would require a loop over the elements of \( A \); however, in almost all cases, Analytica’s array abstraction does this automatically — the expression is simply: \( f(A) \), the result remains indexed by \( I \). However, there are a few cases where Analytica does not automatically array abstract, or it is possible to write a user-defined function that does not automatically array abstract (e.g., by declaring a parameter to be of type **Atom**, see page 340). For example, Analytica does not array abstract over functions such as **Sequence**, **Split**, **Subset**, or **Unique**, since these return unindexed lists of varying lengths that are unknown until the function evaluates. Suppose we have the following variables defined (note: \( A \) is an array of text values):
We wish to split the text values in A and obtain a two dimensional array of letters indexed by Index_1 and Index_2. Since Split does not array abstract, we must do each row separately and re-index by Index_2 before the result rows are recombined into a single array. This is accomplished by the following loop.

```
FOR Row := Index_1 DO Array(Index_2, SplitText(A[Index_1=Row], ', '))
```

resulting in

```
Index_1 ▼, Index_2 ▲
<table>
<thead>
<tr>
<th></th>
<th>1</th>
<th>2</th>
<th>3</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>A</td>
<td>B</td>
<td>C</td>
</tr>
<tr>
<td>2</td>
<td>D</td>
<td>E</td>
<td>F</td>
</tr>
<tr>
<td>3</td>
<td>G</td>
<td>H</td>
<td>I</td>
</tr>
</tbody>
</table>
```

Reducing memory requirements

In some cases, it is possible to reduce the amount of memory required for intermediate results during the evaluation of expressions involving large arrays. For example, consider the following expression:

```
MatrixA: A two dimensional array indexed by M and N.
MatrixB: A two dimensional array indexed by N and P.
Average(MatrixA * MatrixB, N)
```

During the calculation, Analytica needs memory to compute MatrixA * MatrixB, an array indexed by M, N, and P. If these indexes have sizes 100, 200, and 300 respectively, then MatrixA * MatrixB contains 6,000,000 numbers, requiring over 60 megabytes of memory at 10 bytes per number.

To reduce the memory required, use the following expression instead:

```
For L := M Do Average(MatrixA[M=L]*MatrixB, N)
```

Each element MatrixA[M=L]*MatrixB has dimensions N and P, needing only 200x300x10 = 600 kilobytes of memory at a time.

For the special case of a dot product (see “Dot product of two matrices”), for an expression of the form Sum(A*B,I), it performs a similar transformation internally.

While ( Test ) Do Body

While evaluates Body repeatedly as long as Test <> 0. For While ... to terminate, Body must produce a side-effect on a local variable that is used by Test, causing Test eventually to equal 0. If Test never becomes False, While will continue to loop indefi-
For and While loops and recursion

definitely. If you suspect that may be happening, type Control+. (Control+period) to interrupt execution.

**Test** must evaluate to an atomic (non-array) value; therefore, it is a good idea to force any local variable used in **Test** to be atomic valued. **While** is one of the few constructs in Analytica that does not generalize completely to handle arrays. But, there are ways to ensure that variables and functions using **While** support Intelligent Arrays and probabilistic evaluation. See page 361 for details.

**While** returns the final value found in the last iteration of **Body** or Null if no iterations occur. For example:

```
(Var x := 1; While x < 10 Do x := x+1) → 10
(Var x := 1; While x > 10 Do x := x+1) → Null
```

Using **While** often follows the following pattern:

```
Var x[] := ...;
While ( FunctionOf(x) ) Do {
... x := expr;
... }
returnValue
```

**Iterate( x₁, xᵢ, bstop, maxIter, warn )**

Suppose the definition of variable 𝑋 contains a call to **Iterate**: **Iterate** initializes 𝑋 to the value of 𝑥₁. While stopping condition **bstop** is False (zero), it evaluates expression 𝑥ᵢ, and assigns the result to 𝑋. Given the optional parameter **maxIter**, it will stop after **maxIter** iterations and, if **warn** is True, issues a warning — unless it has already been stopped by **bstop** becoming True. If **bstop** is an array, it only stops when all elements of **bstop** are True.

**Iterate** is designed for convergence algorithms where an expression must be recomputed an unknown number of iterations. **Iterate** (like **Dynamic**) must be the main expression in a definition — it cannot be nested within another expression. But it may, and usually will, contain nested expressions as some of its parameters. **Iterate** (again like **Dynamic** and unlike other functions) may, and usually will, mention the variable 𝑋 that it defines within the expressions for 𝑥₁ and **bstop**. These expressions may also refer to variables that depend on 𝑋.

If you use **Iterate** in more than one node in your model, you should be careful that the two functions don't interact adversely. In general, two nodes containing **Iterate** should never be mutual ancestors of each other. Doing so makes the nesting order ambiguous and can result in inconsistent computations. Likewise, care must be taken to avoid similar ambiguities when using interacting **Iterate** and **Dynamic** loops.

**Tip** You can usually write convergence algorithms more cleanly using **While**. One difference is that **While** requires its stopping condition **Test** to be an atom, where **Iterate** allows an array-valued stopping condition **bstop**. Nevertheless, it is usually better to use **While** because you want it to do an appropriate number of iterations for each element of **bstop**, rather than continue until all its elements are True. But, with **While** you will need to use one of the tricks described on and after page 361 to ensure the expression fully supports array abstraction.
Recursive functions

A recursive function is a function that calls itself within its definition. This is often a convenient way to define a function, and sometimes the only way. As an example, consider this definition of factorial:

```
Function Factorial2(n: Positive Atom)
Definition: IF n > 1 THEN N*Factorial2(n-1) ELSE 1
```

If its parameter, `n`, is greater than 1, `Factorial2` calls itself if with the actual parameter value `n-1`. Otherwise, it simply returns 1. Like any normal recursive function, it has a termination condition under which the recursion stops — when `n <= 1`.

Tip

The built-in function `Factorial` does the same, and is fully abstractable, to boot. We define `Factorial2` here as a simple example to demonstrate key ideas.

Normally, if you try to use a function in its own definition, it will complain about a cyclic dependency loop. To enable recursion, you must display and set the Recursive attribute:

1. Select the Attributes dialog from the Object menu:

2. Select Functions from the Class menu in this dialog.

3. Scroll down the list of attributes and click Recursive twice, so that it shows √, meaning that the recursive attribute will be displayed for each function in its Object window and the Attribute panel.

4. Check OK to close Attributes dialog.

For each function for which you wish to enable recursion:

5. Open the Object Window for the function by double-clicking its node (or select the node and click the Object button)

6. Type 1 into its Recursive field, thus:
As another example, consider this recursive function to compute a list of the prime factors of an integer, \( x \), equal to or greater than \( y \):

\[
\text{Function Prime_factors}(x, y: \text{Positive Atom})
\]

\[
\text{Definition:}
\]

\[
\text{Var } n := \text{Floor}(x/y);
\]

\[
\text{IF } n < y \text{ THEN } [x]
\]

\[
\text{ELSE IF } x = n \times y \text{ THEN Concat([y], Factors(n, y))}
\]

\[
\text{ELSE Prime_factors}(x, y+1)
\]

\[
\text{Factors(60, 2) } \rightarrow [2, 2, 3, 5]
\]

In essence, \text{Prime_factors} says: Compute \( n \) as \( x \) divided by \( y \), rounded down. If \( y \) is greater than \( n \), then \( x \) is the last factor, so return \( x \) as a list. If \( x \) is an exact factor of \( y \), then concatenate \( x \) with any factors of \( n \), equal or greater than \( n \). Otherwise, try \( y+1 \) as a factor.

\textbf{Tip} To prevent accidental infinite recursion, it will stop and give a warning if the stack reaches a depth of 256 function calls.

\section*{Local indexes}

You can declare a local index in the definition of a variable or function. It is possible that the value of the variable or value returned by the function is an array using this index. This is handy because it lets you define a variable or function that creates an array without relying on an externally defined index.

The construct, \textbf{Index} \( i := \text{indexExpr} \) defines an index local to the definition in which it is used. The expression \textit{indexExpr} may be a sequence, literal list, or other expression that generates an unindexed array, as used to define a global index. For example:

\[
\text{Variable PowersOf2} := \text{Index } j := 0..5; 2^j
\]

The new variable \text{PowersOf2} is an array of powers of two, indexed by the local index \( J \), with values from 0 to 5:
Chapter 21 Procedural Programming

Ensuring array abstraction

The vast majority of the elements of the Analytica language (operators, functions, and control constructs) fully support Intelligent Arrays — that is, they can handle operands or parameters that are arrays with any number of indexes, and generate a result with

Dot operator: \( a . i \)
The dot operator in \( a . i \) lets you access a local index \( i \) via an array \( a \) that it dimensions. If a local index identifies a dimension of an array that becomes the value of a global variable, it may persist long after evaluation of the expression — unlike other local variables which disappear after the expression is evaluated.

Even though local index \( J \) has no global identifier, you can access it via its parent variable with the dot operator, '.', for example:

\[
PowersOf2.J \rightarrow [0, 1, 2, 3, 4, 5]
\]

When using the subscript operation on a variable with a local index, you need to include the '.' operator, but do not need to repeat the name of the variable:

\[
PowersOf2[J=5] \rightarrow 32
\]

Any other variables depending on \( PowersOf2 \) may inherit \( J \) as a local index — for example:

\[
\text{Variable } P2 := PowersOf2/2
\]

\[
P2[J=5] \rightarrow 16
\]

Example using a local index

In this example, \( \text{MatSqr} \) is a user-defined function that returns the square of a matrix — i.e., \( A \times A' \), where \( A' \) is the transpose of \( A \). The result is a square matrix. Rather than require a third index as a parameter, \( \text{MatSqr} \) creates the local index, \( I_2 \), as a copy of index \( i \).

\[
\text{Function } \text{MatSqr}(a: \text{Array}; i, j: \text{Index})
\]
\[
\text{Definition := Index } I_2 := \text{CopyIndex}(i); \text{Sum}(a \times a[i=I_2], j)
\]

The local variable, \( I_2 \), in \( \text{MatSqr} \) is not within lexical scope in the definition of \( Z \), so we must use the dot operator '.' to access this dimension. We underline the dot operator for clarity:

\[
\text{Variable } Z := \text{Var } XX := \text{MatSqr}(X, \text{Rows}, \text{Cols});
\]
\[
\text{Sum}(XX \times Y[I=XX.I2], XX.I2)
\]
the appropriate dimensions. Thus, most models automatically obtain the benefits of array abstraction with no special care.

There are just a few elements that do not inherently enable Intelligent Arrays — i.e., support array abstraction. They fall into these main types:

- Functions whose parameters must be atoms (not arrays), including `Sequence`, `m..n`, `SplitText`. See page 360.

- Functions whose parameter must be a vector (an array with just one index), such as `CopyIndex`, `SortIndex`, `Subset`, `Unique`, and `Concat` when called with two parameters.

- The `While` loop, which requires its termination condition to be an atom.

- `If b Then c Else d`, when condition `b` is an array, and `c` or `d` may give an evaluation error.

- Functions with an optional index parameter that is omitted, such as `Sum(x)`, `Product`, `Max`, `Min`, `Average`, `Argmax`, `SubIndex`, `ChanceDist`, `CumDist`, and `ProbDist`. See page 363.

When using these constructs, you must take special care to ensure that your model is fully array-abstractable. Here we explain how to do this for each of these five types.

**Functions expecting atomic parameters**

Consider this example:

```plaintext
Variable N := 1..3
Variable B := 1..N
B → Evaluation error:
One or both parameters to Sequence(m, n) or m .. n are not scalars.
```

The expression `1..N`, or equivalently, `Sequence(1, N)`, cannot work if `N` is an array, because it would have to create a nonrectangular array containing slices with 1, 2, and 3 elements. Analytica does not allow nonrectangular arrays, and so requires the parameters of `Sequence` to be atoms (single elements).

Most functions and expressions that, like `Sequence`, are used to generate the definition of an index require atomic (or in some cases, vector) parameters, and so are not fully array abstractable. These include `Sequence`, `Subset`, `SplitText`, `SortIndex` (if the second parameter is omitted), `Concat`, `CopyIndex`, and `Unique`.

Why would you want array abstraction using such a function? Consider this approach to writing a function to compute a factorial:

```plaintext
Function Factorial2
Parameters: (n)
Definition: Product(1..n)
```

It works if `n` is an atom, but not if it is an array, because `1..n` requires atom operands. However, in this version, using a `For` loop, will work fine:

```plaintext
Function Factorial3
Parameters: (n)
Definition: FOR m := n DO Product(1..m)
```

The `For` loop repeats with the loop variable `m` set to each atom of `n`, and evaluates the body `Product(1..m)` for each value. Because `m` is guaranteed to be an atom, this works fine. The `For` loop reassembles the result of each evaluation of `Product(1..m)` to create an array with all the same dimensions as `n`. 
Atom parameters and array abstraction

Function Factorial3
Parameters: (n: Atom)
Definition: Product(1..n)

Index K := 1..6
Factorial3(K) →

Notice that Atom does not require the actual parameter K to be an atom when the function is called. If K is an array, as in this case, it repeatedly evaluates the function Factorial3(n) with n set to each atom of array K. It then reassembles the results back into an array with the same indexes as parameter K, like the For loop above. This scheme works fine even if you qualify several parameters of the function as Atom.

In some cases, a function may require a parameter to be an vector (have only one index), or have multiple dimensions with specified indexes. You may use “Array qualifiers” on page 342 to specify this. With this approach, you can ensure your function will array abstract when new dimensions are added to your model, or if parameters are probabilistic.

While and array abstraction

The While b Do e construct requires its termination condition b to evaluate to be an atom — that is, a single Boolean value, True (1) or False (0). Otherwise, it would be ambiguous about whether to continue. Again, Atom is useful to ensure that a function using a While loop array abstracts, as it was for the Sequence function. Here’s a way to write a Factorial function using a While loop:

Function Factorial4
Parameters: (n: Atom)
Definition:

VAR fact := 1; VAR a := 1;
WHILE a < n DO (a := a + 1; fact := fact * a)
In this example, the Atom qualifier assures that \( n \) and hence the While termination condition \( a < n \) is an atom during each evaluation of Factorial4.

Consider this example:

\[
\text{Variable } X := -2..2 \\
\text{Sqrt}(X) \rightarrow [\text{NAN}, \text{NAN}, 0, 1, 1.414]
\]

The square root of negative numbers -2 and -1 returns NAN (not a number) after issuing a warning. Now consider the definition of A:

\[
\text{Variable } Y := (\text{IF } X>0 \text{ THEN } \text{Sqrt}(X) \text{ ELSE } 0) \\
Y \rightarrow [0, 0, 0, 1, 1.414]
\]

For the construct IF a THEN b ELSE c, a is an array of truth values, as in this case, so it evaluates both b and c. It returns the corresponding elements of b or c, according to the value of condition a for each index value. Thus, it still ends up evaluating Sqrt(X) even for negative values of x. In this case, it returns 0 for those values, rather than NAN, and so it generates no error message.

A similar problem remains with text processing functions that require a parameter to be a text value. Consider this array:

\[
\text{Variable } Z := [1000, '10,000', '100,000']
\]

This kind of array containing true numbers, e.g., 1000, and numbers with commas turned into text values, often arises when copying arrays of numbers from spreadsheets. The following function would seem helpful to remove the commas and convert the text values into numbers:

\[
\text{Function RemoveCommas}(t) \\
\text{Parameters: } (t) \\
\text{Definition: Evaluate(TextReplace(t, ',', ''))}
\]

\[
\text{RemoveCommas}(Z) \rightarrow
\]

Evaluation Error: The parameter of Pluginfunction TextReplace must be a text while evaluating function RemoveCommas.

TextReplace doesn’t like the first value of z, which is a number, where it’s expecting a text value. What if we test if t is Text and only apply TextReplace when it is?

\[
\text{Function RemoveCommas}(t) \\
\text{Parameters: } (t) \\
\text{Definition: IF IsText(t)} \\
\text{THEN Evaluate(TextReplace(t, ',', '')) ELSE t}
\]

\[
\text{RemoveCommas}(Z) \rightarrow \text{(same error message)}
\]

It still doesn’t work because the IF construct still applies ReplaceText to all elements of t. Now, let’s add the parameter qualifier Atom to t:

\[
\text{Function RemoveCommas}(t) \\
\text{Parameters: } (t: \text{Atom}) \\
\text{Definition: IF IsText(t)} \\
\text{THEN Evaluate(TextReplace(t, ',', '')) ELSE t}
\]

\[
\text{RemoveCommas}(Z) \rightarrow
\]
Ensuring array abstraction

This works fine because the **Atom** qualifier means that **RemoveCommas** breaks its parameter \( t \) down into atomic elements before evaluating the function. During each evaluation of **RemoveCommas**, \( t \), and hence **IsText** \( (t) \), is atomic, either True or False. When False, the **If** construct evaluates the **Else** part but not the **Then** part, and so calls **TextReplace** when \( t \) is truly a text value. After calling **TextReplace** separately for each element, it reassembles the results into the array shown above with the same index as \( z \).

Several functions have index parameters that are optional, including **Sum**, **Product**, **Max**, **Min**, **Average**, **Argmax**, **SubIndex**, **ChanceDist**, **CumDist**, and **ProbDist**. For example, with **Sum** \( (x, i) \), you can omit index \( i \), and call it as **Sum** \( (x) \). But, if \( x \) has more than one index, it is hard to predict which index it will sum over. Even if \( x \) has only one dimension now, you might add other dimensions later, for example for parametric analysis. This ambiguity makes the use of functions with omitted index parameters array abstractable.

There is a simple way to avoid this problem and maintain reliable array abstraction: *When using functions with optional index parameters, never omit the index!* Almost always, you know what you want to sum over, so mention it explicitly. If you add dimensions later, you'll be glad you did.

**Tip**

When the optional index parameter is omitted, and the parameter has more than one dimension, these functions choose the **outer index**, by default. Usually, the outer index is the index created most recently when the model was built. But, this is often not obvious. We designed Intelligent Arrays specifically to shield you from having to worry about this detail of the internal representation.

To provide detailed control over array abstraction, the **For** loop can specify exactly which indexes to use in the iterator \( x \). The old edition of **For** still works. It requires that the expression \( a \) assigned to iterator \( x \) generate an index — that is, it must be a defined index variable, **Sequence** \( (m, n) \), or \( m..n \). The new forms of **For** are more flexible. They work for any array (or even atomic) value \( a \). The loop iterates by assigning to \( x \) successive subarrays of \( a \), dimensioned by the indexes listed in square brackets. If the square brackets are empty, as in the second line of the table, the successive values of iterator \( x \) are atoms. In the other cases, the indexes mentioned specify the dimensions of \( x \) to be used in each evaluation of \( e \). In all cases, the final result of executing the **For** loop is a value with the same dimensions as \( a \).
The same approach also works using `Var` to define local variables. By putting square brackets listing indexes after the new variable, you can specify the exact dimensions of the variable. These indexes should be a subset (none, one, some, or all) of the indexes of the assigned value `a`. Any subsequent expressions in the context are automatically repeated as each subarray is assigned to the local variable. In this way, a local variable can act as an implicit iterator, like the `For` loop.

```
Var Temp[I1,I2,...] := X;
```

## References and data structures

A **reference** is an indirect link to a value, an atom or an array. A variable can contain a single reference to a value, or it can contain an array of references. Variables and arrays can themselves contain references, nested to any depth. This lets you create complex data structures, such as linked lists, trees, and non-rectangular structures. Use of references is provided by two operators:

- `\e` is the **reference operation**. It creates a reference to the value of expression `e`.
- `#e` is the **dereference operation**. It obtains the value referred to by `e`. If `e` is not a reference, it issues a warning and returns Null.

An example:

```
Variable M
Definition: 100

Variable Ref_to_M
Definition: \ M
```

The result of `Ref_to_M` looks like this:
You can double-click the cell containing «ref» to view the value referenced, in this case:

You can also create an array of references. Suppose:

\[
\begin{align*}
\text{Index } K \\
\text{Definition: } 1..5 \\
\text{Variable } K_{\text{square}} \\
\text{Definition: } K^2 \\
K_{\text{square}} & \\
\rightarrow \\
\text{Variable } \text{Ref}_\text{to}_{\text{Ksquare}} \\
\text{Definition: } \backslash K_{\text{square}} \\
\text{Ref}_\text{to}_{\text{Ksquare}} & \\
\rightarrow \\
\end{align*}
\]

If you click the «ref» cell, it opens:
Managing indexes of referenced subarrays: \[[i, j,...] e\]

More generally, you can list in the square brackets any indexes of \(e\) that you want to be indexes of each subarray referenced by the result. The other indexes of \(e\) (if any) will be used as indexes for the referencing array. Thus, in the example above, since there were no indexes in square brackets, the index \(K\) was used as an index of the reference array. If instead we write:

\[
\begin{align*}
\text{Variable} & \quad \text{Ref_Ksquare_array} \\
\text{Definition:} & \quad \begin{Bmatrix} & \end{Bmatrix} K\text{square} \\
K\text{square} & \rightarrow \\
\end{align*}
\]

It creates a similar result to \(K\text{square}\), since \(K\) is the only index of \(K\text{square}\).
To summarize:

<table>
<thead>
<tr>
<th>[ e ]</th>
<th>Creates a reference to the value of expression <em>e</em>, whether it is an atom or an array.</th>
</tr>
</thead>
<tbody>
<tr>
<td>( [e] )</td>
<td>Creates an array indexed by all indexes of <em>e</em> containing references to all atoms from <em>e</em>.</td>
</tr>
<tr>
<td>( [i] e )</td>
<td>Creates an array indexed by any indexes of <em>e</em> other than <em>i</em> of references to subarrays of <em>e</em> each indexed by <em>i</em>.</td>
</tr>
<tr>
<td>( [i,j,...] e )</td>
<td>Creates an array indexed by any indexes of <em>e</em> other than <em>i</em>, <em>j</em> ... of references to subarrays of <em>e</em> each indexed by <em>i</em>, <em>j</em> ....</td>
</tr>
</tbody>
</table>

In general, it is better to include the square brackets after the reference operator, and avoid the unadorned reference operator, as in the first row of the table. Being explicit about which indexes to include will generally lead to expressions that array abstract as intended.

**IsReference( X )**

Is a test to see whether its parameter *x* is a reference. It returns True (1) if *x* is a reference, False (0) otherwise.

**Using references for linked lists: Example functions**

Linked lists are a common way for programmers to represent an ordered set of items. They are more efficient than arrays when you want often to add or remove items, thereby changing the length of the list (which is more time consuming for arrays). In Analytica, we can represent a linked list as an element with two elements, the item — that is, a reference to the value of the item — and a link — that is, a reference, to the next item:

```
Index Linked_list
Definition: ['Item', 'Link']
```

**Function LL_Put(x, LL)**

Description: Puts item *x* onto linked list *LL*.

```
Function LL_Put(x, LL)
Description: Puts item x onto linked list LL.
Definition: 
```

```
Array(Linked_List,[\x,LL])
```

**Function LL_Get_Item(LL)**

Description: Gets the value of the first item from linked list *LL*.

```
Function LL_Get_Item(LL)
Description: Gets the value of the first item from linked list LL.
Definition: # Subscript(#LL, Linked_list, 'Item')
```

**Function LL_length(LL)**

Parameters: (LL: Atom)

Description: Returns the number of items in linked list *LL*.

```
Function LL_length(LL)
Parameters: (LL: Atom)
Description: Returns the number of items in linked list LL
Definition: VAR len := 0;
WHILE (IsReference(LL)) BEGIN
   LL := subscript(#LL, Linked_List, "Next");
   len := len + 1
END;
len
```

**Function LL_from_array(a, i)**

Parameters: (a; i: Index)
Description: Creates a linked list from the elements of array a over index i

Definition:

VAR LL := NULL;
Index iRev := Size(i) .. 1;
FOR j := iRev
    DO LL := LL_Push(LL, Slice(a, i, j));
LL

See Linked List lib.ANA for these and other functions for working with linked lists.

Miscellaneous functions

These functions include a variety of tools especially useful for advanced applications, including several (Error, MsgBox) useful for building interactive applications. For example, you can write wizards to automate certain modeling tasks, asking the user for options and input values.

**Error(message)**

Displays an evaluation error, with the specified message, for example:

```
Variable Xyz :=
Error('There seems to be some kind of problem')
Xyz →
```

If you call Error() in a check attribute, it will show the error message you supply it for the warning dialog, instead of the default message when the check fails, letting you tailor a message to the application.

**Evaluate(t)**

Evaluates a text value t as though it were an expression in a definition. It returns the value resulting from evaluating the expression. For example:

```
Evaluate('10M /10') → 1M
```

If t contains any syntax errors, it returns Null; it does not flag a syntax error.

One use for Evaluate is to convert (coerce) a text representation of a number into the number itself, for example:

```
Evaluate('100M') → 100M
```
Like most other functions, it returns the deterministic (mid) or probabilistic value, according to the context in which it is called.

The context in which b parses its text parameter t is quite different from the definition of the variable that calls Evaluate. This creates some subtleties. Consider:

```
Variable A := 99
Variable B := (VAR A := 0; Evaluate(‘A + 1’))
B → 100
```

Evaluate assumes a global context for evaluating its parameter: Variable A in the evaluated text ‘A + 1’ refers to the global A, not the local A declared in B. More generally:

- Evaluate(t) parses the text in t at the time it evaluates it, in a context separate from the expression in which the Evaluate(t) appears — e.g., the definition of B above.
- Thus, text t cannot refer to local variables, indexes, or function parameters defined in the context in which Evaluate(t) appears.
- Text t may itself define and use local variables, but these will not be available outside t.
- Automatic dependency maintenance does not work for variables mentioned in evaluated text. For example:

```
B := A+1
C := Evaluate(‘A+1’)
```

When A changes, it automatically ensures that B is updated when necessary, but does not know that C also depends on A.

Text t may itself be an expression that creates a text value to be evaluated by Evaluate. This text expression appears in the definition of V and is not subject to the above limitations, so, for example:

```
Variable V :=(Var x:= ’10’; Evaluate(x & x))
V → 1010
```

**IgnoreWarnings(expr)**

Evaluates its parameter expr, and returns its value, while suppressing most warnings that might otherwise be displayed during the evaluation. It is useful when you want to evaluate an expression that generates warnings, such as divide by zero, that you know are not important in that context, but you do not want to uncheck the option Show Result Warnings in the Preferences dialog, because you do want to see warnings that may appear in other parts of the model. For more on that option, see “Preferences dialog” on page 59. For more on warnings, see “Warning” on page 413.

**MsgBox(message, buttons, title)**

Displays a standard popup model dialog box with the user-supplied message, buttons (see numerical codes below), and title parameters. Analytica pauses until the user presses a button on the message box. It returns a number, depending on which button the user presses (see below).

The optional buttons parameter is a number that controls which buttons to display, as follows:
0 = OK only
1 = OK and Cancel (the default if buttons is omitted)
2 = Abort, Retry and Ignore
3 = Yes, No and Cancel
4 = Yes and No
5 = Retry and Cancel

To display an icon, add one of the following numbers to the `buttons` parameter:

16 = Critical (white X on red circle)
32 = Question
48 = Exclamation
64 = Information

`MsgBox` returns a number depending on which button the user presses:

1 = OK
2 = Cancel (stops any further evaluation)
3 = Abort
4 = Retry
5 = Ignore
6 = Yes
7 = No

Here are some examples:

`Msgbox('OK, I'm done now.',0+64,'Information')` →

![Information](image1)

`Msgbox('Uh uh! Looks like trouble!',5+16, 'Disaster')` →

![Disaster](image2)

`Msgbox('Do you really mean that?', 3+32, 'Critical question')` →

![Confirmation](image3)
ShowProgressBar

Declaration  
`ShowProgressBar(title, text: Text atomic; p: number atomic)`

Description  
Displays or updates a programmable dialog containing a progress bar. The first time it is called with `p<1`, the dialog appears. When `0<=p<1`, a Cancel button is displayed and the progress meter is updated to the indicated proportion, allowing computation to continue while it is visible. If the user presses Cancel, the computation is aborted. When `p=1`, an OK button is shown and the dialog waits until OK is pressed to return and then disappears. The dialog is also removed when `p>1` or a computation completes.

Example  
```plaintext
var xOrig := X;
var result :=
for n[] := @Scenario do {
    ShowProgressBar( "Progress", "Computing Across All Scenarios", (n-1)/size(scenario) );
    WhatIf( Y, X, xOrig[@Scenario=n] )
};
ShowProgressBar( "Progress", "Done", 1 );
result
```

Today( )

Returns the current date as the number of days that have elapsed since Jan 1, 1904.
Tip When you evaluate this function, your result probably will be cached. The cached result will become out-of-date if the date changes during the Analytica session.
Analytica Enterprise extends the Professional edition with these features:

- **Database access**: Functions to read and write data from and to ODBC databases and external files.
- **Creating buttons**: Objects that users click to run scripts that change the model, and assign new values to variables.
- **Huge arrays**: Expand arrays with indexes of over 30,000 elements, limited only by memory.
- **Save models as Browse-only**: Models that let end users of models modify only variables designated as inputs.
- **Hide definitions**: Prevent end users from viewing data or algorithms that are confidential or proprietary.
- **Performance Profiler**: A library to see which variables and functions take the most CPU time or memory.
- **RunConsoleprocess**: A function that calls another Windows application as subprogram from Analytica.
Accessing databases

Analytica Enterprise provides several functions for querying external databases using **ODBC**. ODBC (Open Database Connectivity) is a widely used standard for connecting to relational databases, on either local or remote computers. It uses queries in Structured Query Language (SQL), pronounced "sequel", to read from and write to databases.

**Overview of ODBC**

SQL is a widely used language to read data from and write data to a relational database. A relational database organizes data in two-dimensional tables, where the **columns** of a table serve as fields or labels, and the **rows** correspond to records, entries, or instances. In Analytica, it is more natural to refer to the columns as **labels** and rows as **records**. For instance, an address book table might have the columns or labels: LastName, FirstName, Address, City, State, Zip, Phone, Fax, E-mail, and each individual would occupy one row or record in that table.

The result of an SQL query is a two-dimensional table, called a **result table**. The rows are the records matching the criteria specified by the query. The columns are the requested fields.

Analytica Enterprise provides functions that accept an SQL query, using standard SQL syntax, as a text-valued parameter. These functions return the result of the query as an array with two dimensions: Its rows are indexed by a **record index**, and the columns are indexed by a **label index**. So, the basic structure of an Analytica model for retrieving a result table is:

![Diagram of database structure](image)

Each of these three nodes could require the information from the **Result_Table**. For example, the definition of the record index would require knowing how many records (rows) are in the result table; the label index may need to read the names of the columns — although, often they are known in advance; and of course, the **Result_Table** needs to read the table. The Database library provides the functions, **DBQuery**, **DBLabels**, and **DBTable** to define these variables. These functions work in concert to perform the query only once (when the record index is evaluated), and share the result table between the nodes.

For the address database example above, we can obtain the record index as **Individuals**, the label index as **Address_fields**, and the resulting table as **Address_fields**, as follows:
Index Individuals := DBQuery(Data_source,'SELECT*FROM Addresses')
Index Address_fields := DBLabels(Individuals)
Variable Address_fields := DBTable(Individuals, Address_fields)

In the above example, the record index is defined using DBQuery(), the label index is defined using DBLabels(), and the result table is defined using DBTable(). Each function is described below.

To specify a data source query, two basic pieces of information must always be known: The data source identifier, and the SQL query text. These two items are the parameters to the DBQuery() function, and are discussed in the following two subsections.

**DSN and data source**

A **data source** is described by a text value, which may contain the Domain Service Name (DSN) of the data source, login names, passwords, etc. Here, we describe the essentials of how to identify and access a data source. These follow standard ODBC conventions. For more details, consult one of the many texts on ODBC.

**Tip**

You must have a DSN already configured on your machine. If not, consult with your Network Administrator. See “Configuring a DSN” below.

The general format of a data source identification text is (the single quotes are Analytica's text delimiters):

'ver1=value1; attr2=value2; attr3=value3;'

For example, the following data source identifier specifies the database called 'Automobile Data', with a user login 'John' and a password of 'Lightning':

'DSN=Automobile Data; UID=John; PWD=Lightning'

If a database is not password protected, then a data source descriptor may be as simple as:

'DSN=Automobile Data'

If a default data source is configured on your machine (consult your database administrator), you may specify it as:

'DSN=DEFAULT'

Some systems may require one login and password for the server, and another login and password for the DBMS. In this case, both can be specified as:

'DSN=Automobile Data; UID=John; PWD=Lightning; UIDDBMS=JQR; PWDDBMS=Thunder'

You can use the **DRIVER** attribute to specify explicitly which driver to use, instead of letting it be determined automatically by the data source type. For example:

'DSN=Automobile Data; DRIVER=SQL Server'

Instead of embedding a long data source connection text inside the DBQuery() statement, you can define a variable in Analytica whose value is the appropriate text value. The name of this variable can then be provided as the argument to DBQuery(). Another alternative is to place the connection information in a file data source (a .DSN file). Such a file would consist of lines such as:

**DRIVER** = SQL Server
**UID** = John
**PWD** = Lightning
**DSN** = Automobile Data
Assuming this data is in a file named MyConnect.DSN, the connection text can be specified as:

'FILEDSN=MyConnect.DSN'

In some applications, you may wish to connect directly to a driver rather than a registered data source. Some drivers may allow this as a way to access a data file directly, even when it is not registered. Also, some drivers may provide this as a way of interrogating the driver itself. To perform such a connection, use the driver keyword. For example, if the Paradox driver accepts the directory of the data files as an argument, you may specify:

'DRIVER={Paradox Driver};DIRECTORY='D:\CARS'

The specific fields used here (UID, PWD, UIDDBMS, PWDDBMS, DIRECTORY, etc.) are interpreted by the ODBC driver, and therefore depend on the specific driver used. Any fields interpreted by your driver are allowed.

If you do not wish to embed the full DSN in the connection text, a series of dialogs will pop up when the DBQuery() function is evaluated. For example, you can leave the UID and PWD (user name and password) out of your model. When the model is evaluated, Analytica will prompt you to enter the required information. Explicitly placing information in your model eliminates the extra dialog. A blank connection text may even be used, in which case you will need to choose among the data sources available on your machine when the model is being evaluated. Although the user can form the DSN via the graphical interface at that point, the result is not automatically placed in the definitions of your Analytica model. However, you may be able to store the information in a DSN file (depending on which drivers and driver manager you are using). You may also be able to register data sources on your machine from that interface.

### Configuring a DSN

To access a database using ODBC, you must have a Data Source Name (DSN) already configured on your machine. In general, configuring a DSN requires substantial database administration expertise as well as the appropriate access permissions on your computer and network. To configure a data source, you should consult with your Network Administrator and/or your database product documentation. The general task of configuring a DSN is beyond the scope of this manual.

If you find you must configure a DSN yourself, the process usually involves the following steps (assuming your database already exists):

1. Select the ODBC icon from the Windows Control Panel.
2. Select the User DSN, System DSN, or File DSN tab depending on your needs. Most likely, you will want System DSN. Click the **Add** button.
3. Select the driver. For example, if your database is a Microsoft Access database, select Microsoft Access Driver and click **Finish**.
4. You will be led through a series of dialogs specific to the driver you selected. These will include dialogs that will allow you to specify the location of your database, as well as the DSN name that you will use from your Analytica model. An example is shown here:
Specifying an SQL query

You may use any SQL query as a text parameter within an Analytica database function. SQL queries can be very powerful, and may include multiple tables, joins, splits, filters, sorting, and so on. We give only a few simple examples here. If you are interested in more demanding applications, please consult one of the many excellent texts on SQL.

The SQL expression to select a complete table in a relational database, where the table is named `VEHICLES`, would be:

`'SELECT * FROM vehicles'`

Tip

SQL is case insensitive, but Analytica is case sensitive for labels of Column names.

To select only two columns (make and model) from this same table and sort them by make:

`'SELECT make, model FROM vehicles ORDER BY make'`

These examples provide a starting point. When using multiple tables, one detail to be aware of is that it is possible in SQL to construct a result table with two columns containing the same label. For example:

`'SELECT * FROM vehicles, companies'`

where both tables for vehicles and companies contain a column labeled 'Id'. In this case, you will only be able to access one (the first) of the two columns using `DBTable()`.

Thus, you should take care to ensure that duplicate column labels do not result. This can be accomplished, for example, using the `AS` keyword, for example:

`'SELECT vehicles.Id AS vid, companies.Id AS cid, * FROM vehicles, companies'`

For users that are unaccustomed to writing SQL statements, products exist that allow SQL statements to be constructed from a simple graphical user interface. Many databases allow queries to be defined and stored in the database. For example, from Microsoft Access, one can define a query by running Access and using the Query Wizard graphical user interface. The query is given a name and stored in the database. The name of the query can then be used where the name of a table would normally appear, for example:
To retrieve a result table from a data source, you need:

1. The data source connection text.
2. The SQL query. These are discussed in the previous two sections. For illustrative purposes, suppose the connection text is `DSN=Automobile Data`, and the SQL statement is `SELECT * FROM vehicles`. Obtain the relational `Result_table` thus:

   ```
   Index Records := DBQuery('DSN=Automobile Data',
   'SELECT * FROM vehicles')
   Index Labels := DBLabels(Records)
   Variable Result_table := DBTable(Records, Labels)
   ```

   You can now display `Result_table` to examine the results.

   This basic procedure can be repeated for any result table. The structure of the model stays the same, and just the connection text and SQL query text change.

### Separating columns in a model

It is often more convenient for further modeling to create a separate variable for each column of a database table. Each column variable uses the same record index. For example, we might create separate variables for `Make`, `Year`, and `Car model` from the `vehicles` database table:

```
Index Records := DBQuery('DSN=Automobile Data',
'SELECT * FROM vehicles')
Variable Make := DBTable(Records, 'make')
Variable Model_Year := DBTable(Records, 'year')
Variable Car_Model := DBTable(Records, 'model')
```

In this case, the record index is still defined using `DBQuery()`, and each column is defined using `DBTable()`. The actual SQL query is issued only once when the record index is evaluated.

Suppose you wished to have `Make`, `Model`, `Year`, `MPG`, etc., as separate Analytica variables, each a one-dimensional array with a common index. For example:

```
Index Records := DBQuery('DSN=Automobile Data',
'SELECT * FROM vehicles')
Variable Make := DBTable(Records, 'make')
Variable Model_Year := DBTable(Records, 'year')
Variable Car_Model := DBTable(Records, 'model')
```

Since `Model` is a reserved word in Analytica, we named the variable `Car_Model` instead of just `Model`. But, the second parameter to `DBTable()` specifies the name of the column as stored in the database. This does not have to be the same as the name of the variable in Analytica.
Alternatively, you can construct a table containing a subset of the columns in a result table. For example, if vehicles has a large number of columns, you might create this variable with only the three columns you are interested in:

```
Variable SubCarTable:= DBTable(Records,['make','model','year'])
```

This table will be indexed by `Records` and by an implicit index (a.k.a. a null index). The first argument to `DBTable()` must always be an indexed defined by `DBQuery()` — remember the SQL query is defined in that node, and this is how `DBTable()` knows which table is being retrieved.

**DBWrite(): Writing to a database**

You can use SQL to change the contents of the external data source from within an Analytica model. Using the appropriate SQL statements, you can add or delete records from an existing database table. You can also add columns, and create or delete tables, if your data source driver supports these operations.

`DBQuery()` cannot alter the data source, because it processes the SQL statement in read-only mode. Instead, use `DBWrite()`, which is identical to `DBQuery()` except that it processes the SQL statement in read-write mode. `DBWrite()` can make any change to the database that can be expressed as an SQL statement, and is supported by the ODBC driver.

To send data from your model into the database, you must convert that data into a text value — more precisely, into an SQL statement. Analytica offers some tools to help this process. Here, we will illustrate a common case — writing a multi-dimensional array to a table in a database. We use the `ODBC_Library.ana` library distributed with Analytica.

Suppose you want to write the value of variable `A`, which is a three dimensional array indexed by `I`, `J`, and `K`, into a relational table named `TableA`, so that other applications can use the data.2-D table

First, we need to convert the 3D array into the correct relational table form. Then we convert the table into the SQL text to write to the database.

Our approach is to first convert the three-dimensional array `A` into a two dimensional table, which we store into `TableA`. `TableA` needs two indexes: `ARowIndex` and `ALabelIndex`. These three variables are defined as follows:

```
Index ALabelIndex := Concat(IndexNames(A),['A'])
Index ARowIndex := sequence(1, Size(A))
Variable TableA := MDArrayToTable(A, ARowIndex, ALabelIndex)
```

`MDArrayToTable(a, i, l)` is described on page 197. `ALabelIndex` evaluates to `['I','J','K','A']`, and `ARowIndex` sets aside one row for each element of `A`. `TableA` is then a table with one row for each element of `A`, where the value of each index for that element is listed in the corresponding column, and the value of that element appears in the final column.

Next, set up `TableA` in the database with the same columns. This is most easily done using the front end provided with your database. For example, if you are using MS Access, start the MS Access program, and from there, create a new table. Alternatively, you could issue the statement

```
DBWrite(DB,'CREATE TABLE TableA(I <text>, J <text>, K <text>, A <text>)')
```
from an Analytica expression (replacing <text> with whatever type is appropriate for your application). Be sure that the column labels in the database table have the same names as the labels of ALabelIndex in the Analytica model.

**Tip**

If you want to use column labels in the database that are different from the Analytica index names: Define ALabelIndex to be a 1-D array, self indexed. Set the Domain of ALabelIndex to be the database labels, and the values of the array to the index names. (The last value is arbitrary).

Our data is now in the form of a 2-D table as needed for a database table. Next we construct the SQL text to write the table to the database. You must choose whether you want to append rows to the existing database table, or replace the table entirely. Or you can replace only selected entries. Your choice affects how you construct the SQL statement. Here, we totally replace any existing data with the new data: After the operation, the database table will be exactly the same as TableA in the Analytica model. The SQL statements for performing the write is:

```sql
DELETE * FROM TableA
INSERT INTO TableA(I,J,K,A) VALUES ('i1','j1','k1','a111')
INSERT INTO TableA(I,J,K,A) VALUES ('i1','j1','k2','a112')
...
```

The first statement removes existing data, since we are replacing it. We follow this by one `INSERT INTO` statement for each row of TableA. The data to the right of the VALUES keyword is replaced by the specific values for indexes I, J, K, and array A (the example above assumes the values are all text values). If your values are numeric, you should note that MSAccess will add quotes around them automatically.

Since writing the table requires a series of SQL statements, we have two options: Evaluate a series of DBWrite() functions, or lump the series of SQL statements into one long text value and issue one DBWrite() statement. In Analytica, the second option is much more efficient for two reasons. First, the overhead of connecting with the database occurs only one time. Second, intermediate result tables do not have to be read from the ODBC driver, while if you issued separate DBWrite() statements, each one would go through the effort of acquiring the result table, only to be ignored.

To allow multiple SQL statements in a single DBWrite() function (or in a single DBQuery() function), Analytica provides an extension to the SQL language. The double semi-colon separates multiple statements. For example,

`'DELETE * FROM TableA ;; SELECT * FROM TableA'`

first deletes the data from the table, and then reads the (now empty) table. When ;; is used, only the last SQL statement in the series returns a result table. Most statements that write to a database return an empty result table.

We are now ready to write the Analytica expression that will construct the SQL statement to write the table to the database. The function to do this already exists in the ODBC_Library. First, use the Add Module item on the File menu to insert the ODBC_Library into your model; then use the WriteTableSql() function, which returns the SQL statement (as a text value) for writing the table to the database. The function requires that I and L contain no duplicates (which should be the case anyway).

Finally, define:

```analytica
Variable Write_A_to_DB := DBWrite(DB, WriteTableSql(A,RowIndex,LabelIndex,'TableA'))
```
Creating an output node to write to a database

`Write_A_to_DB` writes array `A` to the database whenever it is evaluated. But, this happens when the model user causes `Write_A_to_DB` to be evaluated, not necessarily whenever `A` changes. To make it easy for the end user to perform the write, we suggest you make an output node for `WriteToDB`:

1. Select node `Write_A_to_DB` in its diagram.
2. Select the `Make Output Node` command on the `Edit` menu.
3. Move the new output node to a convenient place in the user interface of the model.

Initially, the output node will show the "Calc" button. When you click it, it writes `A` to the database. It also displays the result of evaluating `DBWrite()`, usually an empty window, not very interesting to the user. To avoid this, append "; ‘Done’ " to its definition:

```
Write_A_to_DB := DBWrite(DB, WriteTableSql(A, RowIndex, LabelIndex, ‘TableA’); ‘Done’
```

Now, when you or an end user of the model, clicks `Write_A_to_DB`, after writing `A` to the database, it shows ‘Done’ in the output node. It reverts to the "Calc" button, whenever `A` changes.

Database functions

The Database library on the `Definition` menu contains five functions for working with ODBC databases:

**DBLabels(dbIndex)**

Returns a list of the column labels for the result table. This statement may be used to define an index which can then be used as the second argument to `DBTable()`. The first argument, `dbIndex`, must be defined by a `DBQuery()` statement.

**DBQuery(connectionString, sql)**

Used to define an index variable. The definition of the index should contain only one `DBQuery()` statement. `connectionString` specifies a data source (e.g., ‘DSN=MyDatabase’) and `sql` defines an SQL query.

When placed as the definition of an index variable, `DBQuery()` will be evaluated as soon as the definition is complete. When it is evaluated, the actual query is performed. The resulting result table is cached inside Analytica, to subsequently be accessed by `DBTable()` or `DBLabels()`.

`DBQuery()` returns a sequence `1..n`, where `n` is the number of records (rows) in the result table.

`DBQuery()` should appear only once in a definition, and if it is embedded in an expression, the expression must return a list with `n` elements.

`DBQuery()` processes the `sql` statement in read-only mode, so that the data source cannot be altered as a result of executing this statement. To alter the data source, use `DBWrite()`.
DBTable( $dbIndex$, $column$ )
DBTable( $dbIndex$, $columnList$ )
DBTable( $dbIndex$, $columnIndex$ )

DBTable() is used to get at the data within a result table. The first argument, $dbIndex$, must be the name of a variable (normally an index) in your Analytica model that is defined with a DBQuery() statement. If the second argument, $column$, is a text value, it identifies the name of a column label in the result table, in which case DBTable() returns a 1-D array (indexed by $dbIndex$) with the data for that column. If the second argument is a list of text values (the $columnList$ form), then DBTable() returns a 2-D table with records indexed by $dbIndex$, and columns implicitly indexed (i.e., self-indexed/null-indexed). If the second argument is the name of an Analytica variable (usually an index) whose value evaluates to a list of text values, those text values become the column headings for a 2-D table with columns indexed by $columnIndex$, and rows indexed by $dbIndex$. With this last form, $columnIndex$ may be defined as DBLabels($dbIndex$).

DbTableNames( $connectionString$, $cat$, $sch$, $tab$, $typ$ )

Connects to an ODBC data source and returns catalog data for the data source. $connectionString$ specifies a data source (e.g., ‘DSN=MyDatabase’). $cat$ (catalog names), $sch$ (schema names), $tab$ (table names), and $typ$ (table types) may be patterns if your ODBC driver manager is ODBC 3 compliant. Use ‘%’ as a wildcard in each field to match zero or more characters. Underscore, ‘\_’, matches one character. Most drivers use backslash (‘\’) as an escape character, so that the characters ‘%’, ‘\_’, or ‘\’ as literals must be entered as ‘\%’, ‘\_’, or ‘\\’. $typ$ may be a comma-delimited list of table types. Your data source and ODBC driver may or may not support this call to varying degrees.

Examples
To get all valid catalog names in My db:

DbTableNames(‘DSN=My db’, ‘%’, ‘%’, ‘%’, ‘%’, ‘%’)

To get all valid schemas in My db:

DbTableNames(‘DSN=My db’, ‘%’, ‘%’, ‘%’, ‘%’, ‘%’)

To get all valid table names in My db:

DbTableNames(‘DSN=My db’, ‘%’, ‘%’, ‘%’, ‘%’, ‘%’)

To get all valid table types:

DbTableNames(‘DSN=My db’, ‘%’, ‘%’, ‘%’, ‘%’, ‘%’)

DBWrite($connectionString$, $sql$)

This function is identical to DBQuery() except that the query is processed in read-write mode, making it possible to store data in the data source from within Analytica.

SqlDriverInfo($driverName$)

Returns a list of attribute-value pairs for the specified driver. If $driverName$=‘’ (an empty text value), returns a list of the names of the drivers. $driverName$ must be a text value — it cannot be a list of text values or an index that is defined as a list of text val-
Reading and writing text files

ReadTextFile (filename)

Reads a file filename and returns its contents as a text value. If filename contains no directory path, it will try to read from the current folder, usually the folder containing the current model file. If it doesn't find the file, it will open a Windows Browser dialog box to prompt the user. For example,

```plaintext
Function LinesFromFile(filename : Atom Text)
Definition:
VAR r := SplitText(ReadTextFile(filename), Chr(10));
Index lines :=1..Size(r);
Array(lines, r)
```

This function reads in the file and splits the text up at the end of each line, with the line feed, Chr(10), character. It then defines a local index lines, to be used as the index of the array of lines that it returns.

If you set optional parameter showDialog to true (1), it will always prompt for the file, even if it finds one by that name. Default is not.

WriteTextFile (filename, text:Text; append, warn:Boolean optional; sep:Text optional)

Writes text to the file filename. The filename is relative to the current data directory. It returns the full pathname of the file if it is successful in writing or appending to it. By default, the append flag is False and warn flag is True. If the file doesn't already exist, it creates the file in the current data directory — and if the file does exist, it asks if you want to replace it. If append is True (1), and the file already exists, it appends the text to the end of the file. If warn is False (0), it will not issue a warning before overwriting an existing file when append is False, or when modifying an existing file when append is True.

If text is an array, it writes each element to the file, inserting separator sep between elements, if provided. If text has more than one dimension, you can control the sequence in which they are written by using function JoinText() to join the text over the index you want innermost.

You can write or append to multiple files when filename is an array of file names. If text has the same index(es), it will write the corresponding slice of text to each file — following proper array abstraction.

CurrentDataDirectory()

Returns the file path of the data directory — the directory used by ReadTextFile() and WriteTextFile(), if their filename parameter contains no other path. When starting a model, it is the directory containing the model. Any call to ReadTextFile() or WriteText-
Chapter 22 Analytica Enterprise  

Making a browse-only model and hiding definitions

When you are ready to let others use the models you have created, you may want to save it as browse-only, so that end users can only change the variables you have designated as inputs (by making input nodes for them). You may also want to hide definitions of variables or functions to protect confidential or proprietary data or algorithms. With Analytica Enterprise, you can save models that are locked as browse-only and with hidden definitions, using these steps:

1. Hide selected definitions in your model, for entire model, modules, or by variable.
2. Save your master model file (and any linked submodules) so that you can still view and modify it yourself.
3. Select Save a copy from the File menu, and check Lock and obfuscate and optionally Save as a browse-only model copy to save an obfuscated copy — that is a file scrambled into a non-human-readable form.
4. Distribute the obfuscated copy to your end users.

The third step permanently locks your model so that hidden definitions can never again be viewed in that copy. It is therefore recommended that you save a protected copy of your model, and leave your original model as a master (unprotected) copy. Until the model is stored in an "obfuscated" form (step 3), an end user is not prevented from unhiding your definitions, or from viewing them by other means (e.g., by loading the Analytica model file into a text editor).

Tip

An obfuscated model file cannot be un-obfuscated, even by the original author. If it is locked as browse-only, it can never again be edited. If definitions are hidden, they can never again be viewed or edited. Always place a master copy of your model (and any submodules) in a safe place before making an obfuscated copy!

Hiding and unhiding definitions

To hide the definition of a single variable or function, select its node and select Hide Definition(s) from the Object menu, so it becomes checked. You cannot hide multiple nodes, except by hiding all nodes in a parent module. To hide the definitions of all objects in a module:

1. Select the node of the module in its parent diagram, or open the module and select no nodes inside it.
2. Select Hide Definition(s) from the Object menu, so it becomes checked.

If a variable, function, or module is hidden, when you try to view its definition, it displays:

[Definition is Hidden]
Making a browse-only model and hiding definitions

**Tip**

The definition of a variable with an input node is always visible regardless of whether it or its parent module is marked as Hidden.

**Unhiding and inheritance of hiding**

Definition hiding is inherited down the module hierarchy: If you hide a module, you hide the definitions of all the objects that it contains, including its submodules and all the objects that they contain — unless you explicitly unhide an object or submodule, in which it or the objects it contains will not be hidden. To unhide a variable, function, or module:

1. Select its node in its parent diagram.
2. Select **Unhide Definition(s)** from the **Object** menu, so it becomes checked.

In the module hierarchy shown below, module `Mo1` is hidden, and therefore so are the objects it contains, module `Mo2`, `Va1`, and `Va2`. But module `Mo3` is unhidden, and therefore so are the objects it contains, `Va3` and `Mo4`. However, object `Va4` is itself explicitly hidden:

```
Mo3
   Mo2
      Va2
      Va3
   Mo4
      Va4
Mo1
```

**Tip**

The **Hide Definition(s)** and **Unhide Definition(s)** menu options are disabled if the current model, or any of its linked submodules, has been obfuscated. In this case, obfuscation has locked hiding in place.

After hiding the definitions you want, you can view your model to check everything is as you want. You can still Unhide items if you want to view or edit them. But, after saving the model in obfuscated form, no one, even you, can view hidden definitions or edit any variables that are not inputs, even if they open the model file in a text editor. That’s why it’s important that you save a master copy for your own use.

**Saving an obfuscated copy of your model**

When you are ready to save an obfuscated copy of your model, select **Save a Copy In** from the **File** menu:
Enter a filename that is different than the filename of your master copy, to make sure that you retain an editable version for your self.

Click the **Lock and obfuscate the copy** checkbox at the bottom of the dialog to save the model in an encrypted form that will make any Hidden definitions unviewable, even if you try to edit the file.

Click **Save as a browse-only model** checkbox if you also want to prevent users from changing any variables not designated as inputs. In that case, the model will be locked in browse-only mode, as if it is being run with Analytica Player or Power Player, even if the user runs the model with an Analytica edition that normally allows editing.

A browse-only model is always obfuscated to prevent anyone from editing the source Analytica file. Thus, it automatically checks **Lock and obfuscate the copy** and the **Save in XML format** option is not available.

If you want end users to be able to use other Enterprise features, such as Database access, File reading and writing, Huge Arrays, or Performance Profiling, they will need the Power Player — or their own Enterprise edition.

When a browse-only model (saved as such from Enterprise) is loaded into Analytica Professional, Analytica Lite, or Analytica Professional, it runs it in Power Player mode.

**Warning: Do not obfuscate libraries or linked submodules!**

If you want to create an obfuscated version of your model, embed any libraries or submodules into it, rather than linking them, to avoid accidentally obfuscating them.

**Tip** if you read an obfuscated library or other module into your model, it will result in obfuscating the parent model, as well as any other separately filed submodules or libraries it may contain. So, you could accidentally end up obfuscating your entire model and rendering it uneditable by anyone, including you! Therefore, we strongly recommend that you do not obfuscate any library or module intended to be used by another model; and that you do not try to read an obfuscated library or module into any model.
Huge Arrays

Analytica Enterprise, Optimizer, Power Player, and ADE can manage Indexes and Arrays of up to 100 Million elements in any dimension. The only practical limit on model sizes is the amount of memory. Huge Arrays means they can also handle Sample Size for probabilistic simulation up to this size. (You can set this in the Uncertainty Setup dialog from the Result menu.) This also let you read in large datasets from databases, using the ODBC functions.

Tip
Editions of Analytica other than Enterprise, Optimizer, Power Player, and ADE are limited to index and sample sizes of 32,000 elements.

Creating buttons and scripts

A button is a special kind of object you can add to a diagram. It contains a script that is executed when you press the button (in browse mode). You need Analytica Enterprise (or Optimizer) to create new buttons. You can use buttons with any edition of Analytica.

To make a button
To create a new button, enter edit mode, and drag from the button icon at the right end of the new object toolbar onto the diagram (or press Control+0):

Button script
The button script is in its script attribute. You can view and edit the script in the Attribute panel as above, or its Object window, like any user-editable attribute. Any change to an identifier used in a button script automatically updates the script, just as it does in a definition of a variable or function.

Script language
The script language is similar to the Analytica language used in definitions. Some key differences are:

• A script consists of one or more statements, each on a separate line, with no ";" or other separator between them.
• A statement can be an assignment to change the definition of a global variable — something not allowed in a variable definition.
• A statement in a script can be any expression valid in the Analytica modeling language, including a call to a built-in or user-defined function, as long as it fits on one line.
• A statement or expression in a script must be all on one line. A new line implies a new statement. A script does not accept BEGIN END or parentheses around a sequence of statements.

• A script can call a function that assigns to a global variable. Such a function may be called directly from a script, or indirectly from another function called from a script, and so on recursively. Such a function may not be from in an Analytica variable.

• Script statements can use a wide range of script commands, not available in the normal modeling language. Among other things, these can open or close windows. See http://lumina.com/wiki/index.php/Commands.

Consult the Scripting Guide on Anawiki for details of syntax of scripts.

Tip

If you want a button to perform a complex series of steps, it is usually easiest to define those steps in a function, and call the function from the script, rather than write the steps directly into the script. Function definitions offer several advantages over scripts, including the ability to add inputs by drawing arrows to its node and a more flexible (and familiar) syntax.

Assigning to global variables

Assigning a definition in a script

A statement in a button script may assign to a nonlocal (global) variable, for example:

\[ A := 100 \]

This is not permitted in the definition of a variable, which may only assign to local variables declared within the definition of the variable, to prevent side effects — where evaluating one variable changes the value of another. See “Assigning to a local variable: \( v := e \)” on page 351.

An assignment statement in a script assigns the definition of the variable to the expression assigned, not to the value of the expression. Consider these three statements in a button script, assuming \( A \) and \( B \) are global (i.e., non-local) variables:

\[ A := 1 \]
\[ B := A+1 \]
\[ A := 100 \]

The second assignment changes the definition of \( B \) to the expression \( A+1 \), not the value of the expression, which would be 2. After these three statements, the value of \( B \) is 101, because the third line sets \( A \) to 100, which propagates to the definition of \( B \) is \( A+1 \).

Assigning a value in a script

In the context of an expression rather than a script statement, the assignment

\[ B := A+1 \]

sets variable \( B \) to the value of \( A+1 \), not the expression \( A+1 \). An expression is anything in the definition of a variable or function. You may also include an expression within a script statement simply by enclosing it in parentheses:

\[ A := 1 \]
\[ (B := A+1) \]
\[ A := 100 \]

In this case, after executing this script, the definition of \( A \) is 2 — the value of expression \( A+1 \) in the second line. Since the definition of \( B \) is now 2, not \( A+1 \), the third line, assigning 100 to \( A \) has no effect on \( B \).
Assigning a value in a function

There is an important exception to the rule that you may not assign to globals in a definition: You may assign to a global variable in a function that is called from a button script. It may be called directly or indirectly — that is, called from a function called from a script, and so on recursively:

```plaintext
Variable A := 100
Variable B := 2

Function IncrementA
Parameters: (x)
Definition: A := A + x

Button Add_B_to_A
Script: IncrementA(B)
```

When you press button `Add_B_to_A`, it calls function `IncrementA`, which sets the definition of `A` to the current value of `A+B`, i.e., 102. Like any assignment in a function, it assigns the value not the expression `A+B`.

This kind of global assignment gives you the ability to create buttons and functions to make changes to a model, including such things as modifying existing model values and dependencies.

Save a computed value

One useful application of assigning to a global variable is to save the results of a long computation. Normally, the cached result of a computation is stored until you change any ancestor feeding into the computation, or until you Quit the session. By assigning the result to a global variable, you can save it so that it remains the same when you change an input, or even when you quit and later restart the model.

A common case where this is helpful is a model containing two parts: (1) A time-consuming statistical estimation, neural network, or optimization that learns a parameter set, and (2) a model that applies the learned parameters to classify new instances. After computing the parameters, you can save them into a set of global variables, and then save and close the model. When you restart the model, you can apply the learned parameters to many instances without having to waste time recomputing them.

Consider this example:

```plaintext
Variable Saved_A := 0

Function Save_value(x)
Description: Sets Saved_A to be the value of x.
Definition: Saved_A := x

Button Save_A
Script: Save_value(A)
```

When you click button `Save_A`, it calls function `Save_value(A)`, which saves the value of `A` into global `Saved_A`. `Saved_A` will retain this value if you change `A` or any of its predecessors, or even if you quit the session, saving the model file, and later restart the model. Thus, you won’t have to wait to recompute `Saved_A`. Of course, the value of `Saved_A` will not update automatically if you change any of its predecessors, the way `A` does. You need to click button `Save_A` again to save a new value of `A`.

If the value of `A` is an array with nonlocal indexes, the definition of `Saved_A` will be an edit table, using those indexes. Any subsequent change to those indexes will affect,
and possibly invalidate the table. If you want to make sure this doesn’t happen, you may want to save copies of the indexes, and transform the table to use the saved indexes.

You may assign to any user-editable attribute of a (nonlocal) variable or other object, subject to the same restrictions as assigning a value — i.e., you may do it only in a function called from a script, directly or indirectly. You may not assign to an attribute in the definition of a variable. The syntax is:

\[
\text{<attrib> OF <object> := <text>}
\]

where \text{<attrib>} is the name of an editable attribute, including \text{Title}, \text{Units}, \text{Description}, \text{Definition}, \text{Check}, \text{Domain}, and \text{Author}; \text{<object>} is the identifier of a user-defined, nonlocal object, variable, function, module, etc.; and \text{<text>} is a text value. For example:

```plaintext
Function Retitle(o, t)
Description: Sets the title of object o to text t.
Parameters: (o: Object; t: Atom Text)
Definition: Title OF o := t
```

Variable Gray := 0
Title: Gray

Button Change_title
Script: Retitle(Gray, ‘Earl ’&(Title of Gray))

When you click button \text{Change_title}, it calls function \text{Retitle} applying it to variable \text{Gray}, prefixing the old title of \text{Gray} with ‘Earl ’ to become ‘Earl Gray’. It will do it again each time you press the button. Notice that the object whose attribute you are resetting may be passed to the function, provided the parameter is qualified as an \text{Object} in the parameters declaration.

If the text is an array, it flattens the array into a single text value before the assignment — probably not what you want. So, it is best only to assign atomic text values.

If you want to assign a new definition as text (rather than assigning the value of an expression), you may assign to the definition thus:

```
Definition OF X := Y^2
```

You may use this method to assign new values to various internal attributes, such as \text{Nodelocation}, \text{Nodecolor}, \text{Nodesize}, and \text{NodeFont}, letting you change the way nodes appear on a diagram. Consult the \text{Scripting Guide} on Anawiki for details of syntax.

### EvaluateScript(t)

This function evaluates a text value \text{t} as if it was a script. This means \text{t} can contain script commands, assignments to globals, and other statements permitted in scripts.

---

Avoid using \text{EvaluateScript(t)} except in script functions — that is, functions called from button scripts. This will minimize the danger of undermining the no-side-effects rule.
### Typescript Window

The Typescript window offers an old-fashioned command-line user interface, like the Windows CMD program or a Unix shell: It shows a prompt — the title of the model or module — at the start of each line. You can type in a script command. It will print any results as text, and show another prompt. The typescript is occasionally useful for advanced users who wish to inspect internal details of a model. You may also use it to test out commands that you want to use in a button script.

To open the Typescript window, press `Control+’` (single apostrophe):

![Typescript Window](image)

### Performance Profiler

The Performance Profiler library shows you the computation time and memory space used by each variable and function. If you have a large model that takes a long time to run or uses a lot of memory, you might want to find out which variables or functions are using the Lion's share of the time or memory. As experienced programmers know, the results are often a surprise. With the results from the Performance Profiler, you know where to focus your efforts to make the model faster or use less RAM.

First add **Performance Profiler.ANA** from the **Libraries** folder into your model:

![Performance Profiler Library](image)

Now display the results (table or graph) for the variables whose performance you want to profile. Open the library, and click **Performance profiles**:

![Performance Profiler Results](image)
This table lists the variables and functions by row, with the class of the object, parent module, Bytes of RAM (random access memory), and CPU msecs (milliseconds of time used by the central processing unit). The last column, msecs w ancestors, shows the CPU milliseconds to compute each variable or function including all its ancestors — i.e., the variables and functions it uses. The Profiler shows all variables and functions that use more than 24 bytes of RAM (the minimum) or take more than 1 millisecond to compute. Use Sort objects by to sort the table by any column.

If you want to inspect a variable or function to see why it’s taking so much time or memory, just click its title in the Objects index column to open its Object window.

Update profiles
After computing more results, click this button to update the performance profile to reflect the additional time and memory used.

Zero out times
If you want to look at the incremental time used by additional results, or another computation, first click this button to zero out the times already computed.

Understanding memory usage
For complex definitions, it may use much more RAM while it is computing than it needs to cache the final result — the Profiler reports only the latter. The Bytes show the RAM used to store the value of each variable, Mid, Probabilistic, or both, depending on which it has computed. Typically, an array takes about 12 bytes per number to store. For example, an uncertain dynamic array of numbers, with an index \( I \) of 20 elements, \( \text{Time} \) has 30 elements, and \( \text{Samplesize} = 1000 \), would use about \( 20 \times 30 \times 1000 \times 12 = 7,200,000 \) bytes or 7.2 Megabytes. Analytica uses an efficient representation for arrays with many zeroes (sparse arrays) or many repeated values. An array that is an exact or partial copy of another array may share slices. In such cases, it may actually use less memory than it reports.

Understanding computation time
The CPU time listed is the time it took to evaluate the mid and/or prob value of each variable or function, depending on which type of evaluation it did. It is zero if the results computed did not cause evaluation of the variable or function. A variable is usually only computed at most once each for its mid and prob value. Rare exceptions include when the variable is referenced directly or indirectly in a parameter to Whatif or Whatifall (page 286), which might cause multiple evaluations. A function may be called many times. The CPU time reported is the sum over all these evaluations.

Time and virtual memory
Like most 32-bit applications on Windows, Analytica can use up to 3 Gigabytes of memory. If your computer doesn’t have that much RAM installed, and it needs more than is available, it may use virtual memory — that is, it saves data onto the hard disk. Since
reading and writing a hard disk is usually much slower than RAM, using virtual memory often causes the application to slow down substantially. In this case, finding a way to reduce memory usage below the amount of physical RAM available may speed up the application considerably. Another approach is to install more RAM, up to 4 Gigabytes.

**Performance profiling attributes and function**

The Performance Profiler library uses a function, two attributes, and a command, which are also available for you to write your own functions using memory or time. For an example of how to use them, you can open up the library.

MemoryInUseBy(v) This function returns the number of bytes in use by the cached result(s) for variable v — with the same disclaimer that shared memory may be counted more than once. It includes memory used by mid and prob values if those results have been computed and cached, but it doesn’t force them to be computed if they haven’t been.

These two special read-only attributes:

**EvaluationTime** This attribute returns the time in seconds to evaluate its variable or function, not including the time to evaluate any of its inputs.

**EvaluationTimeAll** This attribute returns the time in seconds to evaluate its variable or function, including the time to compute any of its inputs that needed to be evaluated (and their inputs, and so on.).

**ResetElapsedTime** This command sets these attributes back to zero. Like any command, you may use it in a button script, the Typescript, but not in a regular definition.

Tip These features, including the Performance Profiler are only available for Analytica Enterprise, Power Player, and ADE editions.

**RunConsoleProcess**(program, cmdline, stdIn, block)

This function lets an Analytica model run a console process, that is, start another Windows application. The application or program may be a simple one with no graphical user interface, or it can interact directly with the user. RunConsoleProcess() can provide data as input to the program and return results generated by the application. The program parameter contains text to specify the directory path and name of the program. It can feed input to the program via command line parameters in cmdline, via the stdIn parameter, piped to the StdIn input channel of the program, or via a data file created with WriteTextFile(). Normally, when the program completes, RunConsoleProcess returns a result (as text) any information the program writes to stdOut. Analytica can also use ReadTextFile() to read any results the program has saved as a data file.

**Required parameter**

program Text to specify the directory path and name of the Windows application (program) to run. A relative path is interpreted relative to Analytica’s CurrentDataDirectory. If it cannot find or launch the application, it gives an error message.

**Optional parameters:**
RunConsoleProcess(program, cmdline, stdin, block)

- **cmdline**: Text given input to the program as command line parameters. (It is separated from the `program` parameter to protect against a common type of virus attack.)

- **stdin**: Text to be piped to the `Stdin` input channel of the program.

- **block**: If you omit `block` or set it to True (1), `RunConsoleProcess()` blocks — that is, after calling the process, Analytica stops and waits until the console process terminates and returns a result before it resumes execution. While blocked, Analytica still notices Windows events: If you press `Control+Break` (or `Control+.`) before the process terminates, it kills the process, and ends further computation by Analytica, just as when Analytica is computing without another process.

  If you set `block` to False (0), `RunConsoleProcess()` spawns an independent process that runs concurrently with Analytica. Within Analytica, it returns empty text. Analytica and the spawned process each continues running independently until it terminates. If you press `Control+Break` (or `Control+.`), it interrupts and stops further computations by Analytica, but has no effect on the spawned process. An unblocking process may continue running even after you exit Analytica. Unblocking processes are useful when you want to send data to another application for display, such as a special graphing package or GIS, or for saving selected results. It is difficult for Analytica to get any results or status back from an unblocking process. If you need results back it is usually best to use a blocking process.

- **curDir**: The directory the process should use as its default directory to read and write files. If omitted, it uses the application’s own directory as the default.

- **priority**: Sets the priority that Windows should give the spawned process relative to the Analytica process. The default (0) is the same priority as the Analytica process. Setting it to +1 or +2 raises its priority, taking more of the CPU for the process. -1 or -2 lowers the priority, letting other processes (including Analytica) use more of the CPU.

- **showErr**: Controls the display of error messages from a blocking process. By default, if the process writes anything to `stdErr`, Analytica displays it as an error message when the process terminates. If `showErr`=2 it shows any text in `stdErr` as a warning message. If `showErr`=0, it ignores anything in `stdErr`. Analytica always ignores any error in an unblocking process, which is assumed to control the display of its own errors.

`RunConsoleProcess()` fully supports Intelligent Arrays. If any parameter is passed an array, it runs a separate process for each element of the array. It runs multiple blocking processes sequentially. It runs multiple non-blocking processes concurrently.

---

**Examples**

### Run a VB Script

Suppose the Visual Basic program file `HelloWorld.vbs` is in your model directory and contains:

```vbs
WScript.Echo "Hello World"
```

Your call to `RunConsoleProcess` might look like:
RunConsoleProcess("C:\Windows\System32\CScript.exe",
               "CScript /Nologo HelloWorld.vbs")

The first parameter identifies the program to be launched. You don't need to worry about quoting any spaces in the path name. The second parameter is the command line as it might appear on a command prompt. This expression returns the text value "Hello World".

To send data to the StdIn of the process, include the optional parameter StdIn:

RunConsoleProcess("C:\Windows\System32\CScript.exe",
               "CScript /Nologo HelloWorld.vbs", StdIn: MyDataToSend )

where MyDataToSend is an Analytica variable that gives a text value.

To run a batch file
Suppose the directory C:\Try contains a data file named data.log and a batch file named DoIt.bat containing:

# DoIt.bat -- dump the log
Type data.log

This batch file assumes it is run from the directory C:\Try so does not mention the directory of data.log. From Analytica, you call:

RunConsoleProcess("C:\Windows\System32\Cmd.exe", "Cmd /C DoIt.bat",
               CurDir: "C:\Try")

or you can run it directly:

RunConsoleProcess("DoIt.bat", "DoIt.bat", CurDir: "C:\Try")

To read data from a URL
If you have the program ReadURL.exe (which you can download from the Anawiki), you can use it to read the contents of a web page into Analytica:

RunConsoleProcess("ReadURL.exe", "ReadURL " & url)

where url is a text string as would appear in the address bar of your browser. You can download the ReadURL.exe program by clicking the link and saving. If you save ReadURL.exe into a directory other than CurrentDataDirectory, you will also need to specify its directory path in the program parameter above.
RunConsoleProcess(program, cmdline, stdIn, block)
Appendices

The following appendices shows you:

• How to select an appropriate sample size
• The complete set of Analytica Menus
• The specifications for Analytica
• The list of reserved words and error message types
• Forward and backward compatibility information
• A bibliography
• A list of all the Analytica functions
Appendix A. Selecting the Sample Size

Each probabilistic value is simulated by computing a random sample of values from the actual probability distribution.

You can control the sampling method and sample size by using the Uncertainty Setup dialog box (see “Uncertainty Setup dialog box” on page 232). This appendix briefly discusses how to select a sample size.

There is a clear trade-off for using a larger sample size in calculating an uncertainty variable. When you set the sample size to a large value, the result is less noisy, but it takes a longer time to compute the distribution. For an initial probabilistic calculation, a sample size of 20 to 50 is usually adequate.

How should you choose the sample size $m$? It depends both on the cost of each model run, and what you want the results for. An advantage of the Monte Carlo method is that you can apply many standard statistical techniques to estimate the precision of estimates of the output distribution. This is because the generated sample of values for each output variable is a random sample from the true probability distribution for that variable.

Uncertainty about the mean

First, suppose you are primarily interested in the precision of the mean of your output variable $y$. Assume you have a random sample of $m$ output values generated by Monte Carlo simulation:

$$\left( y_1, y_2, y_3, \ldots, y_m \right)$$

You can estimate the mean and standard deviation of $y$ using the following equations:

$$\bar{y} = \frac{1}{m} \sum_{i=1}^{m} y_i$$

$$s^2 = \frac{1}{m-1} \sum_{i=1}^{m} \left( y_i - \bar{y} \right)^2$$

This leads to the following confidence interval with confidence $\alpha$, where $c$ is the deviation for the unit normally enclosing probability $\alpha$:

$$\left( \bar{y} - c \frac{s}{\sqrt{m}}, \bar{y} + c \frac{s}{\sqrt{m}} \right)$$

Suppose you wish to obtain an estimate of the mean of $y$ with an $\alpha$ confidence interval smaller than $w$ units wide. What sample size do you need? You need to make sure that:

$$w > 2c \frac{s}{\sqrt{m}}$$

or, rearranging the inequality,

$$m > \left( \frac{2cw}{s} \right)^2$$
To use this, first make a small Monte Carlo run with, say, 10 values to get an initial estimate of the variance of $y$ — that is, $s^2$. You can then use Equation (6) to estimate how many samples will reduce the confidence interval to the requisite width $w$.

For example, suppose you wish to obtain a 95% confidence interval for the mean that is less than 20 units wide. Suppose your initial sample of 10 gives $s = 40$. The deviation $c$ enclosing a probability of 95% for a unit normal is about 2. Substituting these numbers into Equation (6), you get:

$$m > \left( \frac{2 \times 2 \times 40}{20} \right)^2 = 8^2 = 64$$

(7)

So, to get the required precision for the mean, you should set the sample size to about 64.

Another criterion for selecting sample size is the precision of the estimate of the median and other fractiles, or more generally, the precision of the estimated cumulative distribution. Assume that the sample $m$ values of $y$ are relabeled so that they are in increasing order,

$$y_1 \leq y_2 \leq \ldots y_m$$

and $c$ is the deviation enclosing probability $\alpha$ of the unit normal. Then the following pair of sample values constitutes the confidence interval:

$$(y_i, y_k)$$

where

$$i = \left\lfloor mp - c \sqrt{mp(1-p)} \right\rfloor$$

$$k = \left\lceil mp + c \sqrt{mp(1-p)} \right\rceil$$

(8)

(9)

Suppose you want to achieve sufficient precision such that the $\alpha$ confidence interval for the $p$th fractile $Y_p$ is given by $\left( (Y_{ip}, Y_{ik}) \right)$, where $Y_{ip}$ is an estimate of $Y_{p - \Delta p}$, and $Y_{ik}$ is an estimate of $Y_{p + \Delta p}$. In other words, you want $\alpha$ confidence of $Y_p$ being between the sample values used as estimates of the $(p - \Delta p)^{th}$ and $(p + \Delta p)^{th}$ fractiles. What sample size do you need? Ignoring the rounding, you have approximately

$$i = m(p - \Delta p), \quad k = m(p + \Delta p)$$

(10)

Thus,

$$k - i = 2m\Delta p$$

(11)

From Equations (8) and (9) above, you have

$$k - i = 2c \sqrt{mp(1-p)}$$

(12)
Equating the two expressions for $k_i$, you obtain

$$2m\Delta p = 2c\sqrt{mp(1-p)}$$

$$m = p(1-p)\left(\frac{c}{\Delta p}\right)^2$$

For example, suppose you want to be 95% confident that the estimated fractile $Y_{0.90}$ is between the estimated fractiles $Y_{0.85}$ and $Y_{0.95}$. So you have $\Delta p = 0.05$, and $c = 2$. Substituting the numbers into Equation (14), you get:

$$m = 0.90 \times (1 - 0.90) \times (2/0.05)^2 = 144$$

On the other hand, suppose you want the credible interval for the least precise estimated percentile (the 50th percentile) to have a 95% confidence interval of plus or minus one estimated percentile. Then,

$$m = 0.5 \times (1 - 0.5) \times (2/0.01)^2 = 10,000$$

These results are completely independent of the shape of the distribution. If you find this an appropriate way to state your requirements for the precision of the estimated distribution, you can determine the sample size before doing any runs to see what sort of distribution it may be.

**Find** Opens a **Find** dialog box to search for an object by its identifier or title. See “Finding variables” on page 326.

**Find Next** Finds the next object that partially matches the previously defined text value. See “Finding variables” on page 326.

**Find Selection** Finds an object by its identifier that matches the currently selected text. See “Finding variables” on page 326.

**Make Alias** Creates an alias for the selected object(s). See “Alias nodes” on page 55.

**Make Importance** Creates an importance variable (and index) to compute the importance (rank correlation) of all uncertain inputs for the selected variable. See “Importance analysis” on page 282.

**Make Input Node** Creates an input node for the selected node(s). See “Users of your model can then easily view and modify input variables, and view the results, without navigating the details of the model, unless they wish to.” on page 128.

**Make Output Node** Creates an output node for the selected node(s). See “Using output nodes” on page 131.

**Show By Identifier** Show the identifier instead of title of each object in the current diagram, edit table, **Result** window, or **Outline** view. Toggle to show title again.

**Show With Values** Shows the mid values of the variable and all its inputs in each **Object** window. See “Showing values in the Object window” on page 24.

**Attributes** Opens the **Attribute** dialog box to set the visibility of attributes and define new attributes. See “Managing attributes” on page 327.

**Hide Definition(s)** Marks the currently selected node or module as hidden, so that their definitions are invisible. (Analytica Enterprise only)

**Unhide Definition(s)** Unhides the currently selected node or module. This overrides any settings in parent modules to hide definitions. (Analytica Enterprise only)

Definition menu

This menu is hierarchical. Each library lists the functions or other constructs it contains. The middle partition lists built-in libraries. At the bottom, are any libraries you have created or added. If you view and select a subitem when editing a definition, it will paste it into the definition.
Appendix B

Definition menu

Edit Definition Opens the appropriate view for editing the definition of the selected variable. If the variable is defined as a distribution or sequence, the Object Finder opens. If it is defined as a table or probability table, its edit table window opens. Otherwise, an Object window or Attribute panel opens, depending on the Edit attributes setting in the Preferences dialog box. See “Preferences dialog” on page 59.

Edit Time Opens the Object window for the Time system variable. See “The Time index” on page 298.

Paste Identifier Opens the Object Finder dialog box for examining functions and variable identifiers, entering function parameters, and pasting them into definitions. See “Object Finder dialog” on page 121.

Show Invalid Variables Displays a window listing all variables with invalid or missing definitions. See “Invalid variables” on page 329.

Math See “Math functions” on page 146.

Array See Chapter 11, “Arrays and Indexes,” and Chapter 12, “More Array Functions.”

Distribution See Chapter 15, “Probability Distributions.”

Special Displays a list of unusual or less commonly used functions in the Special library.

Statistical See “Statistical functions” on page 274.

Operators Arithmetic, comparison, logical, and conditional operators. See “Operators” on page 142.

System Variables System Variables submenu (see below).

Matrix See “Matrix functions” on page 203.

Text Functions See “Converting a number to text” on page 147.

Financial See “Financial functions” on page 214.

Advanced Math See “Converting a number to text” on page 147.

Optimizer Appears only if you have the Optimizer activated. See Optimizer Guide for more.

Database Appears only in Analytica Enterprise. See “Database functions” on page 381.

your libraries It lists the names of any libraries that you have defined or added to the model, each with a submenu that lists the functions contained in the library. See Chapter 20, “Building Functions and Libraries.”
System Variables submenu

AnalyticaPlatform

In Analytica for Windows, this is ‘Windows’. From Analytica for Macintosh, this is ‘Macintosh’, and from the Analytica Decision Engine this is ‘ADE’.

AnalyticaVersion

An integer encoding the current build number of Analytica being run. In terms of the major release number, minor release number, and sub-minor release number, it is equal to

\[ 10K \cdot \text{Major} + 100 \cdot \text{Minor} + \text{SubMinor} \]

For example, Analytica 3.1 subminor version 1 returns the value 31001.

False

The logical (Boolean) constant that evaluates numerically to zero.

Pi

The ratio of circumference to the diameter of a circle.

Run

The index for uncertainty sampling, defined as \( \text{Sequence}(1, \text{Samplesize}) \).

Samplesize

The number of sample iterations for probabilistic simulation. See “Uncertainty Setup dialog box” on page 232.

Time

The index variable identifying the dimension for dynamic simulation (the \( \text{Dynamic}() \) function). See “The Time index” on page 298.

True

The logical (Boolean) constant that evaluates numerically to nonzero.

Result menu

Show Result

Opens a Result window for the selected object. See “The result window” on page 28.

Mid Value

Displays the Mid or deterministic value. See “Uncertainty views” on page 32.

Mean Value

Displays the mean of the uncertain value. See “Uncertainty views” on page 32.

Statistics

Displays statistics of the uncertain value in a table as set in the Uncertainty Setup dialog box. See “Uncertainty views” on page 32.

Probability Bands

Shows probability bands (percentiles) as set in the Uncertainty Setup dialog box. See “Uncertainty views” on page 32.

Probability Density

Displays a probability density graph for an uncertain value. For a discrete probability distribution, Probability Mass replaces this command. See “Uncertainty views” on page 32.

Cumulative Probability

Displays a cumulative probability graph representing the probability that a variable’s value is less than or equal to each possible (uncertain) value. See “Uncertainty views” on page 32.

Sample

Displays a table of the values determined for each uncertainty sample iteration. See “Uncertainty views” on page 32.

Graph Setup

Displays a dialog box to specify the graphing tool, graph frame, and graph style. See “Graphing roles” on page 91.

Number Format

Displays a dialog box to set the number format for displays of results. See “Number formats” on page 86.
### Diagram menu

<table>
<thead>

</tbody>
</table>

Tip

The options that appear on the help menu will vary depending on your computer setup and the version of Analytica you have. If you do not have Adobe Acrobat installed on your computer, the items that appear above the line will change to only:

- User guide
- Optimizer (if you have purchased the Optimizer)
- Tutorial
Right mouse button menus

Click the right mouse button on one or more nodes, a diagram background, or in other windows to get a menu of useful commands. The list of commands depends on the context. This menu is what you get when you right-click a node.

These two menu options appear only when you right-click one or more nodes. This is the only way to move some nodes in front of others:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bring to Front</td>
<td>Brings the selected object(s) to the front of the drawing order so that if the object(s) overlap any other elements, the object will be visible.</td>
</tr>
<tr>
<td>Send to Back</td>
<td>Sends the selected object(s) to the back of the drawing order so that the selected object(s) are drawn behind any overlapping elements.</td>
</tr>
</tbody>
</table>

Memory usage

The Memory Usage window displays the amount of memory available on your system, as well as the memory currently in use by all applications, including Windows itself. The memory available on your system is the sum of all physical memory installed on your system and the swapfile on your hard disk, which is used to complement the physical memory.
To display the Memory Usage window, select **Show Memory Usage** from the **Window** menu.

This window appears automatically when Analytica runs low on memory.

If you require additional memory to run your model at a given sample size, you can take several steps to increase the amount of memory available to Analytica:

1. Close other open applications.
   
   All applications require a segment of memory to operate, and this reduces the memory available to Analytica.

2. Increase the size of your computer’s swapfile.
   
   Under Windows 95, the swapfile size is dynamically handled by the system by default, and is limited only by the free space available on the hard disk where the swapfile resides. You can manually change swapfile settings in the **Memory** control panel.

   Under Windows NT, the minimum swapfile size is set through the **Hardware** control panel. If your hard disk is full or nearly full, you will need to free space on your hard disk, or select a different hard disk to hold your swapfile, in order to provide more memory for Analytica computations.

3. Finally, consider adding more physical memory to your computer.

   When you save a model, the number of megabytes of peak memory used during the session is also saved. When you open the model, the saved peak memory is compared to the amount of memory allocated to Analytica. If the saved peak memory exceeds 95% of Analytica’s memory allocation, a message will recommend either reducing the sample size (see “Uncertainty Setup dialog box” on page 232) or changing the application memory size (see next section).
Appendix D. Identifiers Already Used

Each object, whether built-in or created by you, must have a unique identifier. This identifier must start with a letter, and can be up to 20 characters including letters, digits, and underscores. If you try to create an identifier already in use, it will warn you and append a digit to make it unique.

To see all identifiers currently in use:

1. Press Control+', to open the Typescript Window
2. Type List, followed by Enter.
Appendix E. Error Message Types

There are several types of error messages in Analytica. Many messages are designed to inform you that something in the model needs to be corrected; some messages indicate that Analytica cannot continue or complete your request. Each error message begins with its message type, one of: warning, lexical, syntax, evaluation, system, and fatal errors.

In general, Analytica allows you to continue working on your model unless it cannot proceed until a problem has been corrected. When you are editing a variable definition, you can request an error message by pressing Alt-Enter or by clicking the definition Warning icon.

Warning  A warning indicates that there is a possible problem. For example:

```
Warning:
  Log of non-positive number.
```

A warning is reported during result evaluation to inform you that continuing may yield unexpected results.

You can suppress evaluation warnings for all variables by disabling the Show result warnings preference (see “Preferences dialog” on page 59). When Show result warnings is unchecked, any warning conditions encountered during result evaluation will be ignored. You can also suppress warnings during evaluation of a single expression with the IgnoreWarnings(expr) function. See “IgnoreWarnings(expr)” on page 369 for details.

If an identifier in a module you are adding to a model has a name conflict with an identifier in the model, you will see a warning similar to the following:

```
Warning:
  Can’t declare Variable Location because the Identifier is already in use as Attribute Location.
  Declare using the Identifier Location1?
```

Lexical error  A lexical error occurs when a component of an expression was expected and is missing or is invalid. For example, if you enter a number with an invalid number suffix, you may get a message similar to the following:

```
Lexical error while checking:
  2sdf
  ^
  Invalid exponent code.
```

Syntax error  A syntax error occurs when an expression contains a syntax mistake. Analytica often reports the mistake together with the fragment of the expression that contained the error. For example:
The following are two common syntax errors:

**Expecting ","**
Indicates a comma is missing, or there are too few parameters to a function.

**Expecting ")"**
Indicates there are too many parameters to a function.

If you attempt to change the identifier for a variable, and the new identifier is assigned to another node, you will see a message similar to the following:

**Syntax error:**
The Identifier "Location" is already in use.

**Evaluation error**  An evaluation error occurs when there is a problem while evaluating a variable, user-defined function, or system function. You are asked if you want to edit the definition of the variable currently being evaluated:

**Error during evaluation of Ch1.**
Do you want to edit the Definition of Ch1?

If a system function expects a specific kind of argument, an error message similar to the following is displayed:

**Evaluation error:**
First parameter of Sysfunction Argmax must be a table.

This message indicates that an argument passed to the function is of a different type or cannot be handled by that function. You may need to redefine a variable being used as an argument to the function, or change an expression being passed as an argument.

**Invalid number**  If a calculation tries to perform a division by zero, it displays a warning with an option to continue calculating. Three possible error codes may be returned as a result of an invalid calculation:
Appendix E

Memory usage

You can test for these results in an expression using "X=INF", Isnan(X), or X=NULL.

<table>
<thead>
<tr>
<th>Code</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>INF</td>
<td>Infinity, such as 1/0</td>
</tr>
<tr>
<td>NAN</td>
<td>Not A Number: Results from invalid functions such as Sqrt(-1), or 0/0.</td>
</tr>
<tr>
<td>NULL (blank)</td>
<td>Displays as a blank cell if the result is a table, or shows the Compute button otherwise. Results from certain functions, such as SubIndex(), when a result is not available.</td>
</tr>
</tbody>
</table>

System error
If you see this message type, please contact Lumina Decision System’s technical support department to report the error. (See inside the front cover for contact information, or go to www.lumina.com.)

Out of memory error
Indicates that Analytica has used up all available memory and cannot complete the current command. If this occurs, first save your model. Before attempting to evaluate again, close some windows, use a smaller sample size, or expand the memory available to Analytica (see “Numbers and arrays” on page 410).
Appendix F. Forward and Backward Compatibility

Backward compatibility

Models created in earlier releases of Analytica can be loaded, viewed, evaluated, and modified with Analytica 4.0. There is no fundamental different in file format, so no file conversion must take place. There are, however, some changes that could affect your results when migrating a model from a previous release to 4.0.

When you are trying a model for the first time in 4.0, the first thing you should do is ensure that Show Result Warnings is checked in the Preferences dialog. While evaluating your model, avoid selecting Ignore Warnings if warnings do appear. If any expression in your model produces a warning that you can live with, surround the expression with IgnoreWarnings(...) to suppress the warning, so that you don’t feel compelled to select the Ignore Warnings button. When you leave warnings on while your model evaluates, many potential backward compatibility issues, if present, will be reported to you.

The most commonly encountered difference is the multiplication of NaN or INF by zero. In earlier releases of Analytica, multiplying INF or NaN by zero results in 0, while now it results in NaN (with a warning, if “Check result warnings” is on). The new 4.0 treatment here is in accordance with the IEEE 754 binary floating point arithmetic standard. It was not uncommon by Analytica 3.1 modelers to zero-out NaNs and INFS with a multiplication by zero. Now you may need to use IF-THEN-ELSE instead. If you find certain results have suddenly changed to NaN in 4.0, this is the likely reason.

There have been many bug fixes in Analytica 4.0, so if for some reason your model utilized an undocumented feature that was really a bug, a change in model behavior could result. There are also numerous uncommon situations where there are syntactic and evaluation differences between the releases. In a correctly functioning model from a previous release, you are unlikely to encounter these, but they are documented in detail on the Analytica Wiki at http://lumina.com/wiki/index.php/Changes_in_4.0_that_could_impact_3.x_models.

Generally when you load a model into Analytica and evaluate uncertain variables in an identical sequence, the identical random samples are returned. (Also, when you reset the random seed, you can reproduce the same sample.) In most, but not all, cases, Analytica 4.0 will return the same sample returned by Analytica 3.1; however, this is not guaranteed, and there are several cases where the sample is different. Although the samples in 4.0 and 3.1 come from the same distribution, the precise points in the random samples may be different, causing changes in your results. Uncertain results inherently have a certain “sampling error” arising from the fact that a finite sample size is used, the these differences, when they occur, are reflecting this sampling error. Two uses of distribution functions that are likely to result in a sampling difference are certain hierarchical uses of distributions, in which the parameters to distribution functions are themselves uncertain, and use of the Truncate function (which now preserves rank order). In the hierarchical cases, several distribution functions are more efficient now, requiring fewer random numbers to be generated when producing the entire sample. In either case, once a different number of pseudo-random numbers are utilized, you will see all samples from that point on changed.

Forward compatibility

It is also possible to run models created or edited in Release 4.0 in earlier releases of Analytica, such as Analytica 3.1, provided you don’t rely functions, features, or functionalities new to Analytica 4.0. The models will load into Analytica 3.1, although may encounter problems during parsing or evaluation in the places where 4.0 features are used. A few 4.0 features may be stripped out of the model if it is re-saved from 3.1,
including, for example, graphing settings for graphs viewed while the model was loaded in 3.1.

There are two issues related to edit tables that could potentially create a problem when loading a model edited with 4.0 into an earlier release of Analytica. If a computed index has changed in the model since the downstream edit tables have been accessed, some edit tables may not yet be fully spliced. When loaded into Analytica 3.1, unsliced edit tables will not successfully parse. To avoid this, prior to saving the model from Analytica 4.0, access the typescript windows by pressing the F12 key and type:

```
SpliceTable all
```

A second issue arises if any of your edit tables have blank (empty) cells. Edit tables with blank cells will not parse in earlier releases, so you must ensure that all cells in your edit tables have value, even if just 0 or null.

In general, because there are so many new features in 4.0, it is likely that you may have to test and debug your model in 3.1 to eliminate the use of new features or functions, if its use in 3.1 is required. Please see “What’s new in Analytica 4.0?” for information on the many things that are new to 4.0.
Appendix G. Bibliography

Written by the original authors of Analytica, this text provides extensive background on how to represent and analyze uncertainty in quantitative models. It includes chapters on:

- Building good policy models
- Categorizing types and sources of uncertainty
- How people make judgments under uncertainty
- Encoding expert judgment in the form of probability distributions
- Choosing a computational method for propagating uncertainty in a model
- Analyzing uncertainty in very large models
- Displaying and communicating uncertainty
- How to tell if representing uncertainty could make a significant difference to your conclusions, or "the value of knowing how little you know"

We recommend the second edition, published 1998, which contains a full chapter on Analytica (Chapter 10). If you have the first edition (1990), we recommend that you ignore Chapter 10, which describes the precursor of Analytica and is quite out of date!

### Appendix H. Function List

</tbody>
</table>
This glossary includes a compilation of terms specific to Analytica as well as statistical terms used in this manual.

**ADE**
See “Analytica Decision Engine.”

**Alias**
A node in a diagram that refers to a variable or other node located somewhere else, usually in another module. An alias permits you to display a variable in more than one module. An alias node is distinguished by having its title in italics. See “Alias nodes.”

**Analytica Browser**
A free edition of Analytica that allows a user to evaluate and view results, and change input fields; however, from Analytica Browser a user cannot enter edit mode or otherwise change the content of a model. Copies of Analytica without a valid registration number run as the Analytica Browser. See “Editions of Analytica”.

**Analytica Decision Engine**
A product sold by Lumina Decision Systems, Inc., separate from Analytica. With the Analytica Decision Engine (ADE), you embed the Analytica computation engine in your web-server backend or in your custom applications built in Visual Basic, C++, Microsoft Office, or any language supporting ActiveX Automation or COM. See “Editions of Analytica”.

**Analytica Enterprise**
An edition of Analytica for users who intend to share data or models with others in their organization. Analytica Enterprise contains all features of Analytica Pro as well as functions for accessing ODBC databases and features for protecting your intellectual property. See “Editions of Analytica”.

**Analytica Professional edition**
The standard, fully functional edition of Analytica. Analytica Pro provides all the features and functionality required to create, edit, and evaluate models. See “Editions of Analytica”.

**Analytica Trial**
A fully functional, but expiring, edition of Analytica. Analytica Trial can be downloaded from the Lumina web site (www.lumina.com) for those wishing to “test drive” the product. Analytica Trial contains the complete functionality of Analytica Pro. After expiration, Analytica Trial converts to Analytica Browser. See “Editions of Analytica”.

**Array**
A collection of values that can be viewed as one or more tables. An array has one or more dimensions; each dimension is identified by an index. See “Introduction to arrays”.

**Array abstraction**
See “Intelligent Array Abstraction.”
Arrow
An arrow or influence from one variable node to another indicates that the origin node affects (influences) the destination node. If the nodes depict variables, the origin variable usually appears in the definition of the destination variable. See “Drawing arrows”.

Arrow tool
The arrow tool, or influence arrow tool, is in the shape of a left-to-right pointing arrow cursor. The arrow tool is used to draw arrows connecting variables to create relations between them. See “Drawing arrows”.

Attribute
A property or descriptor of an object, such as its title, description, definition, value, or inputs. See “Managing attributes”.

Attribute panel
An auxiliary window pane that you can open below a diagram or outline window. Use the Attribute panel to rapidly examine one attribute at a time of any variable in the model, by selecting the variable and then the attribute from a popup menu. See “The Attribute panel”.

Author
An attribute recording the names of the person or people who created the model, or other object.

Behavior analysis
Model behavior analysis is a type of sensitivity analysis in which you specify a set of alternative values for one or more inputs and examine the effect on selected model output variables. It is also known as parametric analysis. See “Analyzing Model Behavior”.

Browse-only models
Analytica Enterprise users can save a copy of their model in a browse-only form. When a browse-only model is loaded into any edition of Analytica, the user cannot enter edit mode, and therefore can only make changes to variables with input nodes. Browse-only models are also obfuscated. See “Making a browse-only model and hiding definitions”.

Browse tool
The browse tool is in the shape of a hand. With the browse tool, you can examine the diagram but cannot make any changes, except to change the values in input nodes. See “Browse mode”.

Chance variable
An uncertain variable that cannot be directly controlled by the decision maker. It is usually defined by a probability distribution. A chance variable is depicted as an oval node. See “Classes of variables and other objects”.

Check
The check attribute contains an expression that checks the validity of the value of a variable. It displays a message when the variable’s value is out of specified bounds. See “Automatic checking for valid values”.
Class
The type of Analytica object: decision, chance, objective, or index variable; function; module; library; form; model. See “Classes of variables and other objects”.

Cloaking
See “Definition Hiding.”

Conditional dependency
A chance variable $a$ is conditionally dependent on another variable $b$ if the probability of a value of $a$ depends on the value of $b$. If $a$ is defined by a probability table, $b$ may be an index of its probability table. See “Add a conditioning variable”.

Constant
A variable whose value is not probabilistic, and does not depend on other variables, such as the number of minutes in an hour. See “Classes of variables and other objects”.

Continuous distribution
A probability distribution defined for a continuous variable — that is, for a real-valued variable. Example continuous distributions are beta, normal, and uniform. Compare to “Discrete distribution.” See “Parametric continuous distributions” and subsequent sections.

Continuous variable
A variable whose value is a real number — that is, one of an infinite number of possible values. Its range can be bounded (for example, between 0 and 1) or unbounded. Compare to “Discrete variable.”

Created
The date and time at which the model was first created. This model attribute is entered automatically, and is not user-modifiable.

Cumulative probability distribution
A graphical representation of a probability distribution that plots the cumulative probability that the actual value of the uncertain variable $x$ will be less than or equal to each possible value of $x$. The cumulative probability distribution is a display option in the Uncertainty View popup menu. See “Cumulative probability”.

Data source
A data source is described by a text value, which may contain the Domain Service Name (DSN) of the data source, login names, passwords, etc. See “DSN and data source”.

Decision variable
A variable that the decision maker can control directly. Decision variables are represented by rectangular nodes. See “Classes of variables and other objects”.

Definition
A formula for computing a variable’s value. The definition can be a simple number, a mathematical expression, a list of values, a table, or a probability distribution. In text format, it is limited in length to 32,000 characters. See “Creating and Editing Definitions”.
Definition Hiding
A feature in Analytica Enterprise for protecting your intellectual property when distribut-
ing models you have created to others. Definition hiding controls whether the end-user
of your model can view the definitions of selected nodes. See “Making a browse-only
model and hiding definitions”.

Description
Text explaining what the node represents in the real system being modeled. It is limited
in length to 32,000 characters. See “Attributes of a function”.

Deterministic table
A deterministic function that gives the value of a variable $x$ conditional on the values of
its input variables. The input must all be discrete variables. The table is indexed by each
of its inputs, and gives the value of $x$ that corresponds to each combination of values of
its inputs. See “Creating a determtable”.

Deterministic value
A variable’s deterministic value, or mid value, is a calculation of the variable’s value
assuming all uncertain inputs are fixed at their median values.

Deterministic (determ) variable
A variable that is a deterministic function of its inputs. Its definition does not contain a
probability distribution. The value of a deterministic variable can be probabilistic if one
or more of its inputs are uncertain. A deterministic variable is displayed as a double
oval. You can also use a general variable (rounded rectangle) to depict a deterministic
variable. See “Classes of variables and other objects”.

Determtable
See “Deterministic table.”

Diagram
See “Influence diagram.”

Dimension
An array has one or more dimensions. Each dimension is identified by an index vari-
able. When an array is shown as a table, the row header (vertical) and column headers
(horizontal) give the two dimensions of the table. See “Introduction to arrays”.

Discrete distribution
A probability distribution over a finite number of possible values. Example discrete dis-
tributions are Bernoulli and the Protable function. Compare to “Continuous distribu-
tion.” See “Parametric discrete distributions”.

Discrete variable
A variable whose value is one of a finite number of possible values. Examples are the
number of days in a month (28, 29, 30, or 31), or a Boolean variable with possible val-
ues True and False. A variable that is defined as a list or list of labels is discrete. Com-
pare to “Continuous variable.”
Domain
The possible outcomes of a variable. The domain has a type as well as value. The possible types are List of Labels, List of Numbers, or Continuous; the default type is Continuous, except for variables defined with the \texttt{Choice()}, \texttt{Probtable()}, and \texttt{Determinable()} functions.

DSN
The Domain Service Name (DSN) provides connectivity to a database through an ODBC driver. The DSN contains the database name, directory, database driver, user ID, password, and other information. See “DSN and data source” on page 375.

Dynamic variable
A variable that depends on the system variable \texttt{Time} and is defined by the \texttt{Dynamic()} function. A dynamic variable can depend on itself at a previous time period, directly or indirectly, through other dynamic variables. See “Dynamic Simulation”.

Edit table
A definition that is a table is also called an edit table because it can be edited. See “Viewing an array as an edit table” and “Editing a table”.

Edit tool
A tool is used to create a new model or to change an existing model. It allows you to move, resize, and edit nodes, and exposes the arrow tool and node palette. The edit tool is in the shape of the normal mouse pointer cursor. See “Creating and editing nodes”.

Excel Graph
The graphing engine of Microsoft Excel®. Users who have Excel installed on their computers can take advantage of Excel Graph to graph results.

Expression
A formula that can contain numbers, variables, functions, distributions, and operators, such as \(0.5\), \(a-b\), or \(\text{Min}(x)\), combined according to the Analytica language syntax. The definition of a variable must contain an expression. See “Using Expressions”.

Expression type
The \texttt{Expression} popup menu, which appears above the definition field, allows you to change the definition of a variable to one of several different kinds of expressions. Expression types include expression, list (of expressions or numbers), list of labels (text values), table, probability table, and distribution. Any definition, regardless of expression type, can be viewed as an expression. See “The Expression popup menu”.

File Info
The name of the file and folders in which the model was last saved.

Filed library
A library whose contents are saved in a file separate from the model that contains it. A filed library can be shared among several models without making a copy for each model. See “Using filed modules and libraries”.

Glossary
Filed module
A module whose contents are saved in a file separate from the model that contains it. A filed module can be shared among several models without making a copy for each model. See "Using filed modules and libraries".

Fractile
The median is the 0.5 fractile. More generally, there is probability $p$ that the value is less than or equal to the $p$ fractile. Quantile is a synonym for fractile. (Fractal is something different!) Compare to "Percentile."

General variable
A variable that can be certain or probabilistic. It is often convenient to define a variable as a general variable without worrying about what particular kind of variable it is. A general variable is depicted by a rounded rectangle node. See "Classes of variables and other objects".

Graph
Format for displaying a multidimensional result. To view a result as a graph, click the Graph button. See also "Table."

Graphing role
An aspect of a graph or chart used to display a dimension (or Index) of an array value. They include the horizontal axis, vertical axis, and key. See "Graphing roles".

Identifier
A short name for a variable used in mathematical expressions in definitions. An identifier must start with a letter, have no more than 20 characters, and contain only letters, numbers, and '_' (underscore, used instead of a space). Each identifier in a model must be unique. Compare to "Title." See "Identifiers and titles".

Importance analysis
Importance analysis lets you determine how much effect the uncertainty of one or more input variables has on the uncertainty of an output variable. Analytica defines importance as the rank order correlation between the sample of output values and the sample for each uncertain input. It is a robust measure of the uncertain contribution because it is insensitive to extreme values and skewed distributions.

Unlike commonly used deterministic measures of sensitivity, this rank order correlation averages over the entire joint probability distribution. Therefore, it works well even for models where the sensitivity to one input depends strongly on the value of another. See "Importance analysis".

Index
An index of an array identifies a dimension of that array. An index is usually a variable defined as a list, list of labels, or sequence. An index is often, but not always, a variable with a node class of Index. See "What is an index?".

Indexes
Plural of index. Indicates a set of index variables that define the dimensions of a table (in an edit table or value).
Index selection area
The top portion of a Result window, containing a description of the result and other information about the dimensions of the result. See “Index selection”.

Index variable
A class of variable, defined as a list, list of labels, or sequence, that identifies the dimensions of an array — for example, in an edit table. An index variable is depicted as a parallelogram node. Variables of other classes whose definition or domain consist of list, list of labels, or sequence can also be used to identify the dimensions of an array, and are sometimes referred to as index variables. See “Classes of variables and other objects”.

Influence arrow
See “Arrow.”

Influence cycle
A cyclic dependency occurs when a variable depends on itself directly or indirectly so that the arrows form a directed circular path. The only cyclic dependencies allowed in Analytica are in variables using the Dynamic() function that contain a time lag on the cycle. See “Influence cycle or loop”.

Influence diagram
An intuitive graphical view of the structure of a model, consisting of nodes and arrows. Influence diagrams provide a clear visual way to express uncertain knowledge about the state of the world, decisions, objectives, and their interrelationships. See “The Object window”.

Innermost dimension
The dimension of an array that varies most rapidly in the Table() function. The innermost dimension is the last index listed in a Table() or Array() function. Compare to “Outermost dimension.”

Input
A variable that appears in the definition of the selected variable. See also “Output.”

Input arrowhead
An arrowhead pointing into a node, indicating that the node has one or more inputs from outside its module. Click the arrowhead for a popup menu of the input variables.

Inputs
A list of the variables or functions on which this variable or function depends. The inputs are determined by the arrows drawn to and the variables or functions referred to in this variable’s or function’s definition or check attribute. See also “Outputs.”

Intelligent Array Abstraction
A powerful key feature of the Analytica Engine that automatically propagates and manages the dimensionality of multidimensional arrays within models.
Key
In a results graph, the key shows the value of the key index variable that corresponds to each curve, indicated by pattern or color.

Kurtosis
A measure of the peakedness of a distribution. A distribution with long thin tails has a positive kurtosis. A distribution with short tails and high shoulders, such as the uniform distribution, has a negative kurtosis. A normal distribution has zero kurtosis. See “Kurtosis(x)”.

Last Saved
The date and time at which the model was last saved. This model attribute is entered automatically, and is not user-modifiable. If the model is new, this field remains empty until the model is first saved.

Library
A model component that typically contains a collection of user-defined functions and/or variables to be shared. See “Libraries”.

List
A type of expression available in the Expression popup menu consisting of an ordered set of numbers or expressions. A list is often used to define index and decision variables. See “Create a list”.

List of labels
A type of expression available in the Expression popup menu consisting of an ordered set of text items. A list of labels is often used to define index and decision variables. See “Creating an index”.

Matrix
A two-dimensional array of numbers with indexes of equal length. See “Matrix functions”.

Mean
The average of the population, weighted by the probability mass or density for each value. The mean is also called the expected value. The mean is the center of gravity of the probability density function.

Median
The value that divides the range of possible values of a quantity into two equally probable parts. Thus, there is 0.5 probability that the uncertain quantity is less than or equal to the median, and 0.5 probability that it is greater than the median.

Mid value
The result of evaluating a variable deterministically, holding probability distributions at their median value. Analytica calculates the mid value of a variable by using the mid value of each input. The mid value is a measure of central value, computed very quickly compared to uncertainty values. Compare “Probvalue.”
Mode
The most probable value of the quantity. The mode is at the highest peak of the probability density function. On the cumulative probability distribution, the mode is at the steepest slope, at the point of inflection. See “Probability density”.

Model
A module, or a hierarchy of linked and/or embedded modules and libraries, on which you work during an Analytica session; the main, or root, module at the top of the module hierarchy. Between sessions, a model is stored in an Analytica document file. See “Models”.

Module
A collection of related nodes, typically including variables, functions, and other modules, organized as a separate influence diagram. A module is depicted in a diagram as a node with a thick outline. See “Classes of variables and other objects”.

Module hierarchy
A model can contain several modules, each one containing details of the model. Each module can contain further modules, containing still more detail. This module hierarchy is organized as a tree with the model at the top. You can view the hierarchical structure in the Outline window. See “Organizing a module hierarchy” and “Show module hierarchy preference”.

Multimodal distribution
A probability distribution that has more than one mode. See “How many modes does it have?”.

Node
A shape, such as a rectangle, oval, or hexagon, that represents an object in an influence diagram. Different node shapes are used to represent different types of variables. See “Classes of variables and other objects”.

Normal distribution
The bell-shaped curve, or Gaussian distribution.

Obfuscated
Saved in a non-human-readable (i.e., encrypted) form. Obfuscation provides a mechanism for protecting intellectual property. Analytica Enterprise users can distribute obfuscated copies of their models to their end-users. In Analytica, obfuscation also has the effect of making settings for definition hiding and/or browse-only mode permanent. See “Making a browse-only model and hiding definitions”.

Object
A variable, function, or module in an Analytica model. Each object is depicted as a node in an influence diagram and is described by a set of attributes. See also “Class,” “Node,” “Attribute,” and “Influence diagram.”

Object Finder
A dialog box used to browse and edit the functions and variables available in a model. See “Object Finder dialog”.

Object window
A view of the detailed information about a node. The Object window shows the visible attributes, such as a node’s type, identifier, and description. See “The Object window”.

Objective variable
A variable that evaluates the overall desirability of possible outcomes. The objective can be measured as cost, value, or utility. A purpose of most decision models is to find the decision or decisions that optimize the objective — for example, minimizing cost or maximizing expected utility. An objective variable is represented by a hexagonal node. See “Classes of variables and other objects”.

ODBC
Open Database Connectivity (ODBC) is a widely used standard for connecting to relational databases, on either local or remote computers, and issuing queries in Standard Query Language (SQL). See “Overview of ODBC” on page 374.

OLE Linking
A standard in the Windows operating system for sharing data between applications. See “Using OLE to link results to other applications”.

Operator
A symbol, such as a plus sign (+), that represents a computational process or action such as addition or comparison. See “Operators”.

Outermost dimension
The dimension of an array that varies least rapidly in the Table() function. The outermost dimension is the first index listed in a Table() or Array() function. Compare to “Innermost dimension.”

Outline window
A view of a model that lists the objects it contains as a hierarchical outline. See “The Outline window”.

Output
A variable whose definition refers to the selected variable. See also “Input.”

Output Arrowhead
An arrowhead pointing out of a node, indicating that the node has one or more outputs outside its module. Click the arrowhead for a popup menu of the output variables.

Outputs
A list of the variables or functions that depend on this variable or function. The outputs are determined by the arrows drawn from this variable or function and the variables or functions in whose definition or check attribute this variable or function appears. See also “Inputs.”

Parameters
The arguments of a function. See “Analyzing Model Behavior”.

Glossary
Parametric analysis
See “Behavior analysis.”

Parent diagram
The diagram for the module that contains this object.

Percentile
The median is the fiftieth percentile (also written as 50%ile). More generally, there is probability \( p \) that the value is less than or equal to the \( p_{th} \) percentile. Compare to “Fractile.”

Probabilistic variable
A variable that is uncertain, and is described by a probability distribution. A probabilistic variable is evaluated using simulation; its result is an array of sample values indexed by Run.

Probability bands
The bands that display the uncertainty in a value by showing percentiles from its distribution — for example, the 5%, 25%, 50%, 75%, and 95% percentiles. On a graph, these often appear as bands around the median (50%) line. Probability bands are also referred to as credible intervals. See “Probability Bands option”.

Probability density function (PDF)
A graphical representation of a probability distribution that plots the probability density against the value of the variable. The probability density at each value of \( x \) is the relative probability that \( x \) will be at or near that value. The probability density function can be displayed for continuous, but not discrete variables. It is a display option in the Uncertainty View popup menu. Compare to “Probability mass function,” which is used with discrete variables. See “Probability density”.

Probability distribution
A probability distribution describes the relative likelihood of a variable having different possible values. See “Probability distributions” and “Probabilistic calculation”.

Probability mass function
A probability mass function is a representation of a probability distribution for a discrete variable as a bar graph, showing the probability that the variable will take each possible value. The probability mass function can be displayed for discrete, but not continuous variables. It is a display option in the Uncertainty mode View menu. Compare to “Probability density function (PDF),” which is used with continuous variables. See “Probability density”.

Probability table
A table for specifying a discrete probability distribution for a chance variable. In a probability table, you specify the numerical probability for each value in the domain of the variable. If the variable depends on (that is, is conditioned by) other discrete variables, each of these conditioning variables gives an additional dimension to the table, so you can specify the probability distribution conditional on the value of each conditioning variable. See “Probtable(): Probability Tables”.

Percentile
The median is the fiftieth percentile (also written as 50%ile). More generally, there is probability \( p \) that the value is less than or equal to the \( p_{th} \) percentile. Compare to “Fractile.”

Probabilistic variable
A variable that is uncertain, and is described by a probability distribution. A probabilistic variable is evaluated using simulation; its result is an array of sample values indexed by Run.

Probability bands
The bands that display the uncertainty in a value by showing percentiles from its distribution — for example, the 5%, 25%, 50%, 75%, and 95% percentiles. On a graph, these often appear as bands around the median (50%) line. Probability bands are also referred to as credible intervals. See “Probability Bands option”.

Probability density function (PDF)
A graphical representation of a probability distribution that plots the probability density against the value of the variable. The probability density at each value of \( x \) is the relative probability that \( x \) will be at or near that value. The probability density function can be displayed for continuous, but not discrete variables. It is a display option in the Uncertainty View popup menu. Compare to “Probability mass function,” which is used with discrete variables. See “Probability density”.

Probability distribution
A probability distribution describes the relative likelihood of a variable having different possible values. See “Probability distributions” and “Probabilistic calculation”.

Probability mass function
A probability mass function is a representation of a probability distribution for a discrete variable as a bar graph, showing the probability that the variable will take each possible value. The probability mass function can be displayed for discrete, but not continuous variables. It is a display option in the Uncertainty mode View menu. Compare to “Probability density function (PDF),” which is used with continuous variables. See “Probability density”.

Probability table
A table for specifying a discrete probability distribution for a chance variable. In a probability table, you specify the numerical probability for each value in the domain of the variable. If the variable depends on (that is, is conditioned by) other discrete variables, each of these conditioning variables gives an additional dimension to the table, so you can specify the probability distribution conditional on the value of each conditioning variable. See “Probtable(): Probability Tables”.

Percentile
The median is the fiftieth percentile (also written as 50%ile). More generally, there is probability \( p \) that the value is less than or equal to the \( p_{th} \) percentile. Compare to “Fractile.”

Probabilistic variable
A variable that is uncertain, and is described by a probability distribution. A probabilistic variable is evaluated using simulation; its result is an array of sample values indexed by Run.

Probability bands
The bands that display the uncertainty in a value by showing percentiles from its distribution — for example, the 5%, 25%, 50%, 75%, and 95% percentiles. On a graph, these often appear as bands around the median (50%) line. Probability bands are also referred to as credible intervals. See “Probability Bands option”.

Probability density function (PDF)
A graphical representation of a probability distribution that plots the probability density against the value of the variable. The probability density at each value of \( x \) is the relative probability that \( x \) will be at or near that value. The probability density function can be displayed for continuous, but not discrete variables. It is a display option in the Uncertainty View popup menu. Compare to “Probability mass function,” which is used with discrete variables. See “Probability density”.

Probability distribution
A probability distribution describes the relative likelihood of a variable having different possible values. See “Probability distributions” and “Probabilistic calculation”.

Probability mass function
A probability mass function is a representation of a probability distribution for a discrete variable as a bar graph, showing the probability that the variable will take each possible value. The probability mass function can be displayed for discrete, but not continuous variables. It is a display option in the Uncertainty mode View menu. Compare to “Probability density function (PDF),” which is used with continuous variables. See “Probability density”.

Probability table
A table for specifying a discrete probability distribution for a chance variable. In a probability table, you specify the numerical probability for each value in the domain of the variable. If the variable depends on (that is, is conditioned by) other discrete variables, each of these conditioning variables gives an additional dimension to the table, so you can specify the probability distribution conditional on the value of each conditioning variable. See “Probtable(): Probability Tables”.
Glossary

Probtable
See “Probability table.”

Probvalue
The probabilistic value of a variable, represented as a random sample of values from the probability distribution for the variable. The probvalue for a variable is based on the probvalue for the inputs to the variable. See also “Probabilistic variable” and compare to “Mid value.”

Quantile
See “Percentile.”

Reducing function
A function that operates on an array over one of its indexes. The result of a reducing function has that dimension removed, and hence has one fewer dimension. See “Array-reducing functions”.

Remote variable
A variable in another module, not shown in the active diagram. Typically a remote variable is an input or output of a node in the active diagram. See “Seeing remote inputs and outputs”.

Result view
A window that shows the value of a variable as a table or graph.

Sample
An array of values selected at random from the underlying probability distribution for a quantity. Analytica represents uncertainty about a quantity as a sample, and estimates statistics, probability density function, and other representations of a probability distribution from the sample. See “Sample”.

Sampling method
A method used to generate a random sample from the probability distributions in a model (for example, Monte Carlo and Latin hypercube). See “Sampling method”.

Scalar
A value that is a single number.

Scatter plot
A graph that plots the samples of two probabilistic variables against each other. See “Scatter plots”.

Self
A keyword used in two different ways:

- Refers to the index of a table that is indexed by itself. Self refers to the alternative values of the variable defined by the table.

- Refers to the variable itself, as a substitute for the variable’s identifier, in a check attribute expression or a Dynamic expression.
Sensitivity analysis
A method to identify and compare the effects of various input variables to a model on a selected output. Example methods for sensitivity analysis are importance analysis and model behavior analysis. See “Sensitivity analysis functions”.

Side effects
Changes to a global variable during evaluation other than those expected in its definition. See “Assigning to a local variable: v := e” on page 351.

Skewed distribution
A distribution that is asymmetric about its mean. A positively skewed distribution has a thicker upper tail than lower tail; and vice versa, for a negatively skewed distribution. See “Is the quantity symmetric or skewed?”. 

Skewness
A measure of the asymmetry of the distribution. A positively skewed distribution has a thicker upper tail than lower tail, while a negatively skewed distribution has a thicker lower tail than upper tail. A normal distribution has a skewness of zero. See “Skewness(x)”. 

Slice
A slice of an array is an element or subarray selected along a specified dimension. A slice has one less dimension than the array from which it is sliced. See “Selecting, slicing, and subscripting arrays”.

Slicer
See “Slicers” on page 93.

SQL
Standard Query Language or SQL is a standard interactive and programming language for getting information from and updating a database. See “Accessing databases” on page 374.

Standard deviation
The square root of the variance. The standard deviation of an uncertainty distribution reflects the amount of spread or dispersion in the distribution.

Suffix
Numbers such as 10K, 123M, or 1.23u are in suffix notation. The suffix letter denotes a power of ten; for example, K, M, and u denote $10^3$, $10^6$, and $10^{-6}$, respectively. See “Suffix characters”.

Symmetrical distribution
A distribution, such as a normal distribution, that is symmetrical about its mean. See “Is the quantity symmetric or skewed?”. 

System function
A function available in the Analytica modeling language. See also “User-defined function.”
Glossary

System variable
A variable that is part of the Analytica modeling language, such as Samplesize or Time.

Table
A two-dimensional view of an array. The array can have more than two dimensions, but only two can be seen at one time. A definition that is a table is also called an edit table. In the Result window, click the Table button to select the table view of an array-valued result.

Tail
The upper and lower tails of a probability distribution contain the extreme high and low quantity, respectively. Typically, the lower and upper tails include the lower and upper ten percent of the probability, respectively. See “Is the quantity symmetric or skewed?”.

Title
The full name of an Analytica object. A variable’s or module’s title is displayed in its node, in window titles, and in object lists. It is limited to 255 characters. The title can contain any characters, including spaces and punctuation. Compare to “Identifier.” See “Edit a node title”.

Uncertain value
See “Probvalue.”

Uniform distribution
A distribution representing an equal chance of occurrence for any value between the lower and upper values.

Units
The increments of measurement for a variable. Units are used to annotate tables and graphs; they are not used in any calculation.

User-defined function
A function that the user defines to augment the functions provided as part of the Analytica modeling language.

Value
See “Mid value.”

Variable
An object that has a value, which may be text, a number, or an array. Classes of variable include decision, chance, and objective. See “The Object window”.

Variance
A measure of the uncertainty or dispersion of a distribution. The wider the distribution, the greater its variance.
